In the permanent general hospitals, which resemble in every way the best civilian institutions, the gastrointestinal service normally occupies about 10 per cent of the capacity of the medical service or about two thirty-two bed wards.

The cantonment type hospitals used in the present mobilization consist of standard units of temporary construction arranged on the pavilion plan. Major Chamberlin³⁹ reports that at the Lawson General Hospital, a new two thousand bed cantonment type institution at Atlanta, Ga., the gastroenterologic section consisted on Jan. 3, 1942 of three wards, two active and one convalescent. Similar sections are in operation at the Tilton General Hospital, Fort Dix, N. J.,⁴⁰

at the Billings General Hospital, Fort Benjamin Harrison, Ind.,⁴¹ and probably in other general hospitals.

Selection, Training and Assignment of Personnel—Professional personnel for the section of gastroenterology is made available as follows. Regular army medical officers who show special aptitude for the work are listed as gastroenterologists in the personnel section of the Surgeon General's Office. They receive their basic training in army hospitals but in accordance with medical department policy have the privilege of obtaining leaves for the purpose of perfecting their professional qualifications elsewhere. Experienced reserve officer gastroenterologists are made available from lists originally assembled by the American Medical Association's Committee on Medical Preparedness and now from the Procurement and Assignment Service in Washington, D. C. Since June 1940 the American Gastroenterological Association, through its Committee on Military Preparedness,⁴² which contains representatives of the Advisory Committee on Gastroenterology of the American Board of Internal Medicine as well as the Section on Gastroenterology and Proctology of the American Medical Association, has assisted the Surgeon General of the Army in recommending qualified gastroenterologists for active duty.

According to a calculation made in 1931, I believe that the correct number of gastroenterologists required for a complete mobilization for war should constitute at least 2 per cent of the total number of medical officers on active duty.

Medical officers are eligible for refresher courses in gastroenterology which are given in the permanent army general hospitals. During such courses, which last one month and include groups of twenty to thirty students from various stations throughout the army, the instructors are enabled to determine the professional and administrative proficiency of their student officers and to decide specifically whether these are capable of operating their respective services on their return to their proper stations.

Nurses assigned to the section of gastroenterology are, as elsewhere in the Army, either members of the regular Army Nurse Corps or of the Reserve, the latter being supplied by the American Red Cross. The gastrointestinal section of the Fitzsimons General Hospital has four nurses three of whom are considered regular members of the unit, the fourth being an "understudy." Enlisted men, often graduates of the School for Medical Technicians at Denver, carry out the various duties of ward orderlies, technical assistants, attendants and ward masters under the supervision of the ward nurse, ward surgeon and chief of the section.

Care of a Typical Case in an Army Hospital—It may be useful to illustrate for the nonmilitary reader the general procedure followed by the army in the care of patients with digestive disease. Such patients are admitted to the gastrointestinal section of an army general hospital either by transfer from another hospital (clearing station, evacuation hospital, station hospital or other general hospital lacking facilities for gastrointestinal cases) or more directly from a neighboring command from "sick call" held by troops stationed in or near the receiving general hospital itself. The patient is then studied according to the plan adopted by the chief of the particular gastrointestinal section.

concerned or in accordance with directives issued from higher authority if there are such. In the course of this "work-up" every diagnostic facility used in the best civilian practice is included. These are available either as part of the gastrointestinal section itself as in the case of test meals, proctoscopes and other procedures, or by close cooperation with other hospital departments such as the roentgen and laboratory services. Gastroscopy by experienced observers is performed either within the gastrointestinal section itself or as part of a general endoscopic service.

All the usual therapeutic procedures are available. The hospital pharmacy carries all essential standard drugs. The dietetic department, consisting of a chief and seven assistant dietitians, supplies the usual therapeutic diets. The services of the surgical and dental staffs are available for consultation and treatment.

In the armed forces every case admitted to the hospital is carefully scrutinized to decide whether the disability in question is or is not "in line of duty." Conditions existing prior to enlistment are obviously not in line of duty. This classification is essential in order to decide claims arising from service connected disabilities and is therefore carefully recorded on hospital records and thus made available for the use of the Veterans Administration.

After hospitalization is completed the patient is disposed of in one of several ways. If completely cured he is returned to full duty either directly or by way of a convalescent camp. If some partial disability persists he may be discharged to a limited duty status. If on the other hand, the soldier is adjudged incapable of all further duty and he has received maximum benefit from his hospitalization he may be discharged from the army on a certificate of discharge for disability. If his condition is unimproved and he requires further treatment, he may be transferred to a veterans hospital for this purpose.⁴³

Research Opportunities—There are many opportunities for medical research in the army. To begin with, there is a remarkable control of clinical material including splendid facilities for the follow-up of cases.

Many problems of clinical importance and practical value already press for solution and many more will become apparent as the war continues. Some examples of topics that might profitably receive consideration are the following. To what extent can a person predisposed to ulcer be utilized for limited service when the war enters the phase of all out effort? The same question can be raised concerning persons who have undergone gastroenterostomy or gastric or intestinal resection. What criteria should be adopted for the classification, utilization and discharge of personnel suffering from digestive neuroses?

What is the value, if any, of the sulfonamide drugs in the treatment of bacillary dysentery? Are they likely to prove superior to the present initial treatment with saline or other cathartics? This problem is presumably one for the combat area. What is the real nature of the occasional upsets of gastroenteritis (vomiting and diarrhea) such as the one described in a British camp⁴⁴ and that reported in this country⁴⁵ in which all the known bacteriologic and food examinations were nega-

tive? The epidemiologic features suggest contact or droplet infection and a possible virus origin.

Finally, what is the status of chronic gastritis? Is it, as has been claimed, a definite service connected disability? Is it susceptible of successful treatment in the army or is it a cause for discharge for disability? The answers to the gastritis problem will, of course, not be forthcoming until after we have seen some hard fighting. However, the basis for study is already available in the assignment of qualified gastroscopists to active duty.

DISABILITY RESULTING FROM DIGESTIVE DISEASE IN SOLDIERS

According to the official record,⁴⁶ there were in the United States forces during the first world war from April 1 1917 to Dec 31, 1919 300,468 cases of digestive diseases out of a total of 3,264,694 cases, making an incidence of 9.2 per cent. It would be most interesting to determine, if possible, how much permanent disability has resulted from this amount of wartime indigestion. Perhaps the best way to get an approximate answer to this question would be to turn to the available medical records of our war veterans. This has been attempted and the data on which the following discussion is based have been supplied through the cooperation of S. M. Moore Jr.,⁴⁶ chief of statistics, and of Dr. Charles M. Griffith,⁴⁷ medical director of the Veterans Administration. This administration, with headquarters in Washington, D. C., operates fifty hospitals technically known as general medical facilities, located in various parts of the United States. Gastroenterology is recognized as a specialty and is practiced in all the facilities. It is operated as a separate section in six of the larger institutions, located at Hines, Ill., Minneapolis, Los Angeles, Pittsburgh, the Bronx, New York, and Dayton, Ohio.

In the fiscal year 1931 there were 11,180 cases of disability from disease of the digestive system excluding cancer. These constituted 3.56 per cent of the total service connected cases and accounted for \$4,750,000, or 2.85 per cent of the total awards for compensation. In the fiscal year 1940 there were 13,981 such cases, representing 4 per cent of the total service connected cases and accounting for \$4,934,000, or 2.96 per cent of the awards for compensation. Since, therefore, digestive diseases occur in from 3.5 to 4 per cent among disabled veterans as against 9.2 per cent among World War soldiers, it may be permissible to conclude that the former figures (3.5 to 4 per cent) represent the residue of chronic or permanent disability resulting from the original acute wartime incidence of gastrointestinal disease.

A comparison of the Veterans Administration figures for 1931 with those for 1940 shows an increase of 25 per cent in the total number of nonmalignant digestive diseases among veterans, an increase of 12 per cent in the percentage of service connected cases and an increase of \$184,000 in the annual compensation for these cases in the intervening nine years.

Peptic ulcers are the most common digestive diseases among veterans. In 1940 there were 4,356 service connected cases with 454 additional non-service connected cases. These drew total monthly awards for compensation of \$176,371. Hemorrhoids ranked second

⁴⁵ Dack G. V. An Epidemic of Acute Digestive Upsets of Unknown Etiology Am. J. Digest. Dis. 8: 210-211 1941.

⁴⁶ Moore S. M. Jr. Personal communications to the author Jan 27 1932 Oct 30 1941.

⁴⁷ Griffith C. M. Personal communications to the author Jan 3 and 16 and Feb 18 1942.

with 2,568 cases and \$48,765 in awards, peritoneal adhesions ranked third with 2,529 cases and \$65,475 in awards, colitis ranked fourth with 1,206 cases and \$34,540 in awards, gastritis ranked fifth with 700 cases and \$10,654 in awards, incontinence of feces ranked sixth with 628 cases and \$25,658 in awards and cholecystitis, surprisingly, ranked seventh with 421 cases and \$12,398 in monthly compensation

Further correlation between army experience and that of the Veterans Administration should help solve some important practical questions. What are the criteria for distinguishing between service connected and non-service connected digestive disabilities? Presumably a dysentery followed by a chronic organic colopathy is in a different category from a cancer that develops at the age of 50. What nondisqualifying disabilities existing prior to enlistment are aggravated by military duty? What are the fairest criteria for disability awards in such cases? Why is cholecystitis apparently so rare in male war veterans? It usually ranks second among organic digestive disease in male civilians.⁴⁸

The data now being assembled by the Selective Service System the Medical Department of the Army and the Veterans Administration, plus the experience already gained in the first world war should constitute a splendid source for a definitive study of the effects of military service on digestion.

SUMMARY

1 Digestive diseases always play a prominent role in military medicine both in peace and in war. The most important of these diseases in the present conflict are the intestinal fluxes, peptic ulcer, digestive neuroses and possibly gastritis.

2 Peptic ulcer ranks high as a cause of disability for military service. It is increasingly common in both the civilian and the military population and leads all other digestive diseases as a cause for discharge from the Regular Army.

3 A critical survey of the present recruiting policies indicates that they are probably effective in excluding ulcer bearing candidates from the U S Army.

4 In addition to excluding dyspeptic persons from the Army by careful recruiting, prophylaxis of digestive disease can be accomplished by immunization against specific intestinal infections, by the supervision of food supplies and by the enforcement of general sanitary measures.

5 The Medical Department of the Army is now prepared to give excellent professional care to soldiers suffering from digestive disease. This is made possible by the proper utilization of specialists and the establishment in the larger military hospitals of well equipped and well organized sections of gastroenterology.

6 Opportunities for research on the relation of digestive disease to military service are available and should be cultivated. Among the topics for investigation are the utilization of ulcer predisposed patients for limited service, the status of chronic gastritis as a service connected disability and the value of chemotherapy in the early treatment of bacillary dysentery.

7 Comparison of records from the first world war with those of the Veterans Administration suggests that of every 9 soldiers who exhibit digestive disease in

active service, 3 or 4 are likely to continue to suffer from a permanent digestive disability.

8 Data now being compiled by the Selective Service System the Medical Department of the Army and the Veterans Administration together with the records of the first world war should constitute excellent source material for future studies on the relation between digestive disease and military service.

145 West Eighth-Sixth Street

ABSTRACT OF DISCUSSION

DR DONALD T CHAMBERLIN, Atlanta, Ga. The basic question in disposing of a soldier with digestive disease is: Can he be returned to duty and tolerate the army ration without recurrence of symptoms? If he cannot, no matter what his diagnosis is, he is of no use to the service. The need for gastroenterologists is probably greater than was anticipated. In the last year of about 1800 patients admitted to the medical service at the Lawson General Hospital, the percentage on the gastroenterologic section was 18, which is higher than any anticipated figures that I have seen. There is some impression that soldiers with peptic ulcer can function in the service. That is erroneous; they cannot. Out of the 147 ulcer patients seen at Lawson, and seen by Captain Berk at Tilton in New Jersey, the average length of service from the day they were inducted to the day they were hospitalized was five months, just about long enough to get them through their preliminary training and get them equipped and clothed and fed. The problem of service connected disability so far is not great because almost all of them have their symptoms prior to induction. We are required to determine accurately when the return symptoms began so that there will be no question whether this man has a service connected disability. That we hope will prevent a repetition of conditions which existed after the last war. We have no first hand knowledge as yet of the influence of combat on production of ulcer in our army. The British figures, after several years of combat, are very similar to ours, with one exception: the high incidence of gastric ulcer in their army as against a very low incidence in ours so far. That problem is interesting.

DR HENRY M THOMAS, JR, Fort George G Meade, Maryland. The digestive disease problem exists in the station hospitals of the army as well as in the general hospitals. Naturally the patients are seen first in the station hospitals and then sent on to the general hospital if necessary. When the case is clear cut we handle it directly and so the statistics that ultimately will be available will include cases from the station hospital as well as the general hospital. The station hospital has relatively the same proportion of gastroenterologic cases as are seen in the general hospital. Peptic ulcer is our major gastroenterologic problem. We have tried to establish clearcut criteria for diagnosis for prognosis and, finally, for disposition. Diagnostically the x-ray examination is most helpful but it does not always give us the answer either from the positive or from the negative point of view, nor are the findings always confirmed by a second x-ray examination. At the moment our main criterion for diagnosis of ulcer is the repeated x-ray finding of persistent deformity or crater. As soon as these patients have made maximum hospital improvement they are discharged from the army. There is in most cases of peptic ulcer a problem arising out of some mental anxiety. This affects the prognosis so adversely that when we find an ulcer in a soldier with a large psychoneurotic element we have a rule of thumb that we give him a certificate of disability discharge. The anxiety often springs from some feature of enforced military service and for this reason does not lend itself to cure in the army. As Major Chamberlin has said, the ulcers practically all existed prior to induction, and therefore are "line of duty." No. Those that develop in the military service we may be able to cure and reclassify from combat units into service command units in the zone of the interior. Dr Kantor's interesting paper emphasizes the need in the army for trained gastroenterologists.

⁴⁸ Rivers, A. B. and Ferreira, A. E. M. Incidence and Causes of Chronic Dyspepsia at Various Ages. Analysis of 4223 Cases. J. A. M. A. 110: 2132-2136 (June 25) 1938.

DR J EDWARD BERK Fort Dix, New Jersey To paraphrase a statement attributed to Napoleon "An army travels on its stomach" Unfortunately, digestive cripples will not make blitzkrieg soldiers or sailors We have learned it and the English have learned it to their dismay Because of this fact we are forced to send back into civil life a goodly proportion of patients with dyspeptic phenomena Practically every one of our ulcer patients is eventually discharged from the army At Tilton General Hospital we make no attempt to prolong hospitalization of the uncomplicated ulcer patient Every patient on discharge is given to understand that despite the fact that he is no longer being hospitalized it is by no means considered that his ulcer is cured He is given a book let containing an outline type of dietary and rules of living and he is strongly urged to place himself in the hands of a physician in civil life Patients with functional gastrointestinal disturbances deserve special mention Our experience so far in the army has been that they comprise a much larger percentage of the admissions to general hospitals than has been the experience of the British and the Canadians Fortunately the army probably has more to offer these patients than any other single group Through a close system of collaboration and cooperation with the field social services of the American Red Cross and a group of competent and interested psychiatrists we are enabled to send back into civil life a large proportion of individuals with functional digestive complaints who in the absence of their stay in the army might have remained digestive invalids These people while being unable to be salvaged for military use, for the most part can still lead useful lives as civilians They are gotten to the point where they eat a regular diet and receive no medication On discharge we instruct those in whom a psychoneurosis is deeply embedded to consult with any one of a number of competent psychiatrists or they are given notes to established psychiatric clinics All of them are urged to see a physician repeatedly to receive the continued reassurance which they need With this type of interest and management these much neglected and maltreated patients will be largely and remarkably benefited

DR RUDOLF SCHINDLER Chicago As a veteran of the last war, although having been on the wrong side I may be entitled to congratulate Dr Kantor for his contribution If soldiers who have acquired chronic abdominal distress under actual combat conditions will now be examined better and treated with more justice than during the last war then in my opinion much credit for such development must be given to him

DR HYMAN I GOLDSTEIN Camden N J Galen and Ambroise Pare one of the greatest war surgeons of all time and Dominique Jean Larrey the greatest French military surgeon of the napoleonic era would perhaps at this moment of our discussions smile and say 'We told you so' During the many battles referred to in Homers Iliad and Odyssey some of the warriors suffered from aggravated gastric disturbances Claudius Galen founder of experimental physiology treated Emperor Marcus Aurelius Antoninus Caesar following his battles for aggravated attacks of indigestion Marcus Aurelius later died in Vienna (probably of gastric ulcer or carcinoma) Aurelius Cornelius Celsus during the time of Tiberius Caesar also knew of such aggravated gastric disturbances for in his "De medicina" he laid down rules for the treatment of ulcer of the stomach and prescribed a special smooth soft diet Celsus knew there was an acid factor in gastric ulcer although not until the discovery by William Prout in 1824 and Bidder and Schmidt in 1852, was hydrochloric acid in the gastric juice demonstrated Finally, Aëtius Amidenus Paul Aeginata Serapion Haly Abbas Avicenna Avenzoar, Rhazes J Actuarius Franciscus of Piedmont, Capivaccius, Verandaeus J Sculietus Riolan and Fernel discussed ulcer of the stomach and treated it as we do today They even used terra sigillata (kaolin or aluminum silicate), our 'modern day therapy'

DR JOHN L KANTOR New York It is a great pleasure to have heard this discussion You will agree that the representatives of the U S Army of this generation do credit to this country and its people The War Department policy at present is to authorize the presence of a gastroenterologist on the professional staff of each station hospital of eight hundred beds or over It is true that it is up to the commanding officer

to decide what officers he wants Captain Berk is to be complimented on his very humane mature and understanding attitude not only toward the ulcer patients but particularly to the neurotic I know of nothing better than the organization he has built up, pulling in the aid of the neuropsychiatrist the Red Cross and the individual civilian practitioners in solving this problem To Dr Goldstein may I say that one can go further back in sanitation than he has and read in the second or third book of the Bible a statement attributed to Moses that 'each man shall carry into battle a little paddle or spade wherewith he can bury that which drops forth from him'

THE OPHTHALMOLOGIST'S PLACE IN THE PREVENTION OF TRAFFIC ACCIDENTS

LOWELL S SELLING M.D., PH.D. DR.PH.
DETROIT

The annual loss of life as the result of war casualties during the year of blitz in England was scarcely more than the equivalent loss of life in traffic in that country Here in the United States the situation still remains serious in spite of rationing, voluntary limitation of the use of cars and the removal of a certain number of drivers from the civilian community

There is a clarion call which has already been recognized by the ophthalmologist that everybody in the community should take part in a continuous crusade for the prevention of traffic injury and death Through the subcommittee of the Section on Ophthalmology of the American Medical Association standards have been set up which have been absorbed into the field of the examination of the driver

Many individual members of the section must have been called on to express an opinion about visual acuity standards in general and more specifically the ability of some individual to drive his car In the program of traffic accident prevention in the community, however, the ophthalmologist has three very clear functions

The first is the one which the section has already recognized and that is the function of setting up acceptable minimum standards to eliminate the dangerous drivers yet permit the reasonably safe drivers to continue on the road

The second function has been recognized by individual ophthalmologists namely the moderating function of the physician to make a decision about an individual's capacity to see with regard to safety on the highway when a driver is threatened with the loss of his license

There is however a third capacity in which the ophthalmologist must prepare himself to serve if he has not already done so and that is to act as adviser to the court and here his attitude must be somewhat different from the second which has been outlined for he must evaluate the question of how much the individual's ocular pathologic condition was responsible for an accident

I have discussed the matter of physicians' obligations in the traffic picture on previous occasions¹ and also certain physiologic aspects of vision² In brief the

¹ From the Psychopathic Clinic of the Recorder's Court Series T No 31

¹ Selling Lowell S and Canty Alan Studies on the Problem Driver City of Detroit Scientific Reports from the Psychopathic Clinic of the Recorder's Court 1 25 27 28 (Nov.) 1941

² Selling Lowell S and Canty Alan Studies on the Problem Driver City of Detroit Scientific Reports from the Psychopathic Clinic of the Recorder's Court 1 30 38 (Nov.) 1941

situation is this. If a patient is suffering from some eye disorder, even if it is only a diminution of visual acuity, how must he be evaluated so that he can (1) be treated, (2) be eliminated from the highway if he is dangerous or (3) be permitted to drive if he is not dangerous even though his defect is untreatable or untreated?

The determination of visual standards is a difficult one to make. Certainly the dicta laid down by the subcommittee on visual standards of drivers of the Section on Ophthalmology have crystallized the thinking of traffic experts in a wholesome fashion.³

In 1939 the American Association of Motor Vehicle Administrators⁴ reported that a vision test was being required at that time of all new applicants in thirty-three states and the District of Columbia. The acuity standards varied considerably and ranged from 20/30 to 20/70 on the Snellen cards. No routine tests were provided for testing the field of vision, for scotomas for muscular imbalance, for binocular vision or for fusion, but color vision, as a rule, has been made a part of the traffic test.

I propose here to take up briefly some of these factors as they have demonstrated themselves in our clinic. I must point out before discussing them, however, that it is very doubtful whether bad vision causes any great number of accidents. It is impossible to know how many cases of drivers with bad vision have been involved in accidents, as in those states which license drivers a certain standard visual acuity is demanded of all at least for the record, which is very high, and in the nonlicensing states there is no way of knowing whether the vision of the driver who was involved in an accident was good or bad at the time of his accident.

Halsey⁵ has pointed out that tests made on drivers with perfect eyesight who wore glasses specifically to impair their vision revealed no material change in the ability to avoid accidents.

I am inclined to agree with this belief of Halsey's. In a study⁶ of 1,900 cases which were selected for referral to the clinic by the traffic judge because of traffic accidents, traffic tickets, physical disability, admittedly poor eyesight or the wearing of glasses that corrected poor vision only 536 of the 1,900 individuals were found to be suffering from a visual defect and many of them were minor in degree. Furthermore, only 329 of the persons with visual defects had bad accidents, and 207 were referred for violations of the law rather than for an accident. Only 21 had visual acuity worse than 20/100 (Snellen) in either eye, of this group 14 had accidents and 7 were nonaccident cases. This indicates that it is improbable that visual acuity as measured on the Snellen chart, Clason acuity meter, or one of the other recognized devices for reading letters of various sizes is adequate per se to evaluate the individual's ability to drive a car.

It must not be forgotten that a person with 20/200 vision can see a car over 800 yards ahead of him without a great deal of difficulty. Movement and lighting conditions, as well as changes of direction by other vehicles, make it even easier to see an object which otherwise might be almost out of sight. A car can be

past the horizon before it is out of perceptual distance of the 20/20 eye. The Snellen charts, as I see them, are devised to detect reading ability at 20 feet distance and cannot simulate movement and projective conditions. Chart visual acuity probably has nothing to do with the ability to judge the speed and distance of such a large object as a car, to avoid such large objects or even to test the driver's ability to predict the conduct of another operator of such a large object who is many yards ahead of the subject's own car.

Chart testing does have one very specific corollary, however. If one cannot read the 20/60 Snellen chart at 20 feet, he cannot read the average direction sign at 300 yards. It takes about that distance for the person with rather slow reaction time to stop his car when he merely sees the shape of the sign. Certainly, however, the person who has 20/200 vision as a rule and in broad daylight can perceive the presence of a sign and can do so in plenty of time to stop and examine it, even though he cannot read it in detail at a greater distance.

Except for the expense which is involved, a sign which has larger letters would be an improvement and would obviate any problem with individuals of poor vision. Stop signs, particularly those which are hexagonal, can be perceived many yards in advance of the place where the stopping is demanded. The clinic's drivers with very poor eyesight have never shown evidence of having had any difficulty in perceiving stop signs. They are usually picked up for some other offense than failure to stop for a boulevard stop or other points where stopping is required.

Inferior visual acuity, however, seems to be important and must not be eliminated as a factor merely because some drivers with extremely bad vision have good records. A driver with bad vision whose judgment and attitude and general physical condition are impaired cannot compensate for his visual acuity, and Lauer and Kotvis⁷ have shown that persons with low visual acuity are older, drive more slowly, have driven fewer types of cars, have observed fewer details on driving and are not as strong physically.

The National Safety Council experts on drivers' examinations are of the opinion⁸ that even if the visual acuity standards are comparatively high the person who is disqualified originally benefits by being fitted with glasses to meet the standards. Thus the candidate is refused his license because he does not have 20/40 or some other equivalent amount of visual acuity and he is fitted with glasses.

This complicates the situation and I think the ophthalmologist would do well to look into the whole picture. As a general rule persons who are turned down by the license examiners do not go to an ophthalmologist to see what the trouble is, to see whether perhaps they have a glaucoma or some disorder of the eye which should be treated. They merely go to an optometrist, who fits them with lenses sufficiently sharp so that they can read the test letters. By doing so they might cause and probably do cause a pronounced anisocoria and also a certain number of distortion effects. For example, the strong cylinder apparently gives "harmonica" vision when the eyes are turned

⁹ Personal communication to the author.

from side to side unless the axis is horizontal. Sometimes there is a distortion of small objects so that these objects seem to move, which causes unnecessarily jerky motions on the part of the driver, particularly the one who has not been wearing his glasses over a period of time.

The visual acuity of some persons who have small scars or minor opacities of which they are not aware which do not interfere particularly with their driving and which come out on a visual acuity test only when the standards are very high cannot be corrected. The difficulty does not come from the failure of the light to fall properly on the retina but rather from the failure of certain rays to reach the retina. In our experience persons with these defects if all other factors are equal are competent to drive but they come back from the optometrist with glasses which cannot correct their visual acuity which in some instances do more harm than good and which in many instances will cause an unnecessary expense.

In license cases it has been customary in the state of Michigan to accept the ophthalmologist's opinion that glasses were not needed but it will require some education of the community to teach examiners that there are instances in which the driver is able to manipulate a motorcar safely even though his visual acuity does not come up to standard.

Only the ophthalmologist is in a position to evaluate ophthalmic phenomena and many ophthalmologists hesitate to pass an individual whose acuity is not up to standard because they feel that if the acuity is not up to the state regulation the driver is unsafe per se.

I believe that our findings disagree with this belief sufficiently strongly so that a visual deficiency in excess of the usual allowance which does not affect the patient's judgment of speed and distance, can be certified safely by the ophthalmologist. The patient's driving record which may be verified by his insurance record and his police record or by the family physician who knows the situation intimately, is important. The family physician's knowledge of the person's driving habits, particularly if he knows the patient has had no accidents and very few close shaves and if the physician considers him a good driver, may aid the ophthalmologist to express an opinion even though the standards which are set up by state authority are not reached. The candidate's attitude, his driving record, his general physical condition and the other eye findings will usually outweigh the mere matter of visual acuity.

The matter of testing visual acuity is difficult too. As long as we leave the tests of visual acuity in the hands of lay examiners as we do now, we are going to have bizarre findings. Sometimes the charts are lighted insufficiently, sometimes there is glare, sometimes the distances are measured improperly, sometimes they are given with inaccurate apparatus, sometimes an attempt is made to give them to illiterates who cannot read, and, lastly, not infrequently the examiner is careless or indifferent. In some states the standards are for single eye acuity when it is obvious that the fused acuities of the two eyes is what is being used by the driver to operate his motorcar.

Although I have no figure to bear this out I am of the opinion that the broken circle test of Ferree and Rand¹⁰ is about the most efficient device that we have

today. It has the disadvantages also of not testing acuity under motorial and projective conditions.

Many private corporations test their drivers' eyes with the Keystone Telebinocular, but Schepler¹¹ indicates in his studies that this device should not be used for purposes of testing drivers' eyes as it is now constructed.

I have pointed out that color vision does not seem to be important in the matter of safe driving.² Color blindness was offered as one of the arguments for setting up the Traffic Clinic. We maintained that the color blind individual probably could not distinguish green from red lights. This has proved to be fallacious. Practically color blind people discriminate the lights first of all from their position on the standard in those towns where this position is constant. Second the amount of brightness in the green and red lenses differs in a recognizable degree. Third, these persons seem to learn to make use of cues from other drivers and from the situation in general.

At any rate, in our accident cases the number of color blind that were found was approximately the same as in the nonaccident group. The clinic has on record a control group of very effective truck drivers who proved to be color blind after having driven for many years without an accident or an arrest. As a matter of fact the two leading safety men in the city of Detroit both of whom drive constantly without an accident are both red-green color blind.

There were more nonaccident cases in the group which has a restricted visual field than accident cases, and the belief that restriction of the visual field is of some significance must be subject to limitation. It must be remembered that the need for peripheral vision is not very great except when crossing blind highways. Unless the driver's speed in crossing such a highway is great even with only 90 degree binocular vision he can see a car coming into the periphery in sufficient time to stop his car safely. In the ordinary two lane highway with 90 degree vision a driver who is going 30 miles an hour can perceive a car coming at right angles to him at the same speed within 500 yards and he is able to stop within that distance.

Most of our cases with limited visual fields are handicapped because of one blind eye, and the monocular driver is one for serious consideration. Certainly the driver with monocular vision and the one with the restricted visual field is deserving of serious consideration, but, even though DeSilva, Frisbee and Robinson¹² point out their importance, one-eyedness does not in itself preclude safe driving in the experience of our clinic. The unocular person is able to compensate by moving his head from side to side by keeping his head turned slightly toward the blind side or by the use of mirrors which compensate for the deficiency so that he has a reasonably good chance of being a safe driver. Here again attitude, general visual capacity and physical capacity are as important as any unitary eye trait findings.

When the ophthalmologist is consulted to determine the safety of a particular individual either because that person wants a license to be granted or because a court wishes an opinion, he must look at the total picture. It is unfortunate that there are not yet enough quanti-

tative data to make precise evaluations, but it is to be expected that some material which can aid the ophthalmologist in evaluating individuals will be available from our clinic in the not too distant future. Even now the ophthalmologist can use his extensive experience in practice, when undoubtedly he has acquainted himself at least casually with the driving behavior of his patients, to form an opinion about the safety of a particular person. The ophthalmologist should not assume however, merely because the candidate has satisfactory visual acuity, that that person is a safe driver.

I think that the ophthalmologist would be wise if he was to be quite circumspect in his expression of an opinion relative to the driver's potential dangerousness. In addition to the factors which I have discussed, the candidate for a license might be very sensitive to glare; he might have a photophobia which would interfere with driving on bright sunshiny days or he might have scotomas, which, although they do not interfere with acuity, could cause a blind reaction at a critical moment.

Last but by no means least, I believe that the ophthalmologist should consider the matter of advising his patient about not driving. It has been reported that patients have walked out of an ophthalmologist's office with mydriatics in their eyes without having been warned that they should not drive home, yet no physician has a right to assume that the patient knows enough about drugs so that his judgment will be good where medicine is concerned. Only too often patients who are suffering from conjunctivitis and other disorders which temporarily interfere with visual acuity are not advised that they should not drive. Even after the enucleation of an eye it seems to me that the vision changes sufficiently so that one must be warned about change in visual perception. If the acuity of the second eye is not satisfactory, one should be advised against driving. It may seem to the ophthalmologist that I am pointing out some rather distasteful obligations, but in the long run any reasonable patient is more appreciative of being advised of the situation than he is resentful.

SUMMARY

I feel that the ophthalmologist's place in the traffic situation is, first, to continue to work on the establishment of visual standards, with the reservation that these standards in themselves must not be considered too final.

Second, the ophthalmologist should make an evaluation of the individual cases so that future driving can be predicted from the whole picture rather than from the point of view of visual acuity alone.

Third, an educational rephrasing of the whole picture is necessary in order to minimize some of the superficial aspects of tests of a driver's vision, which may eliminate from consideration perhaps color blindness, binocular vision and mild restriction of the visual field but which emphasize the need for restriction of driving of those individuals who have acute or chronic conditions which are significant in the driving field. The driving restrictions on a basis of vision should be made by a skilled ophthalmologist and not a lay examiner.

The ophthalmologist can do no less than acquaint himself with the whole literature on visual acuity, visual disease and diseases of vision from the standpoint of the driver if he is to be of real value to traffic court officials, license examiners and others who are trying to expunge the morbid and lethal effect of the automobile.

ABSTRACT OF DISCUSSION

DR S J LDD BRACH, Portland, Maine. Dr Selling's report tends to revolutionize our notions of the essential visual requirements for driving automobiles. Ophthalmologists are asked to recommend standards of vision for many occupations. Oddly they seem to feel no doubt that they are qualified to single out the exact line of the Snellen chart which determines the competence of a swimming teacher, aviator or automobile driver. One of the most painstaking and reasonable reports on requirements for automobile drivers has been submitted by the subcommittee of this section. Yet the members are doubtless aware that it is at best an attempt to translate monocular testing in the dim religious light of a refraction range into binocular driving on the road, and there is no correlation between the two. To illustrate take the case of one of our bankers now 48 years old. With glasses his vision is better than 6/VI. Without them a high mixed astigmatism reduces his central acuity with both eyes open to 6/II. Yet for years he has preferred to drive by day and to play golf and tennis without glasses, possibly because his vision taken in bright daylight with a contracted pupil is 6/VI perfectly adequate for driving, more likely because he has become accustomed to going without glasses outdoors. The change in appearance of objects when glasses are worn presumably nullifies the improved central vision. A similar disturbance in space relations occurred in two fliers whom I examined this winter. Their slightly deficient central acuity obliged them to wear lenses while flying. Yet with these lenses their depth perception was definitely impaired. Analogous to this is aniseikonia. Lancaster tells of a driver who hogged the middle of the highway and carried away the left doorpost of his garage until fitted with size difference lenses. It begins to seem in traffic accidents that many less obvious factors outweigh the customary criteria—visual acuity, fields and color perception. Factual studies such as these of Dr Selling give us a sounder basis than the theoretic considerations previously followed.

DR ALBERT C SNELL, Rochester, N. Y. Throughout the paper Dr Selling uses the term visual acuity when reference is made to the Snellen acuity determinations and uses the term vision in its generic sense when he refers to the complete complex act of seeing. The punctilious and proper use of these terms is not generally followed by most American ophthalmologists, and this careless habit often causes confusion and misunderstanding. Dr Selling points out that industrial capacity is not measured by acuity expressions. And I wish to add that neither do acuity expressions express an equivalent fractional ability of any visual function not even of angular perception. Therefore one should not be surprised when Dr Selling was able to come to the conclusion. Visual acuity does not, per se, evaluate the individual's ability to drive a car—visual acuity has nothing to do with ability to judge the speed and distance. Dr Selling also finds that a standard of 20/40 acuity is too rigid as the minimum required standard for safe driving. I derive satisfaction from the fact that Dr Selling has been able to demonstrate this fact from his clinical observation of drivers. Evidently he has found that one is not one half blind when visual acuity is reduced to 20/40 although some compensation boards still hold to the contrary view. When one considers the nature of the Snellen notation, a simple explanation is presented of Dr Selling's observation that a person with 20/100 is able to drive efficiently and therefore that the Snellen acuity measurement does not measure the driver's aptitude. The ideal Snellen character, as we all know, is a five minute angle character each limb of which subtends one minute; therefore the normal eye can perceive easily a one minute object, since the 20/100 acuity angle is five times the 20/20, a five minute angle, an eye with a 20/100 acuity has an ability to detect an object equivalent in size to a one minute angle for the normal eye. The minimum visual acuity standards which have been established in several states are too rigid. Even those standards which were established by the committee of this section should be used as a guide and not as an ultimate fixed standard to be applied to each person applying for a license to drive an automobile. In my judgment, lay examiners should be instructed in more precise methods of screening in their visual testing.

These should include in addition to routine testing some simple methods of determining coordination of muscles. In the doubtful cases, at least the final question of physical fitness for driving should be determined by the ophthalmologist in cooperation with an internist after a complete physical examination.

DR HOWARD S. SELLINE, Detroit. My motive in presenting this paper was primarily to get expert opinion and the two discussers, I feel gave me an insight which I could not otherwise have as to the ophthalmologist's point of view. I have a secondary motive, for I am hoping that you will give further consideration to the elimination of vision testing by policemen and others who are not competent. Even such a simple procedure as that which Dr Snell suggests a simple test for muscular balance to be given by these license examiners is impossible, as most lay examiners do not have enough intelligence quotient to be able to do such a test correctly. Then there is the problem of the optometrist who is passing out glasses without helping the traffic situation. If the Section on Ophthalmology can do anything to aid in correcting some of the false conceptions that have arisen in this field, it will be doing a great deal in behalf of safety.

SUCCINYL-SULFATHIAZOLE

AN ADJUVANT IN SURGERY OF THE
LARGE BOWEL

EDGAR J. POTH, PH.D., M.D.

Associate Professor of Surgery, University of Texas Medical Branch
Galveston, Texas

The ideal intestinal antiseptic should be poorly absorbed from the alimentary canal and should have strong antibacterial local action. A compound, succinyl-sulfathiazole¹ which has properties approximating these specifications has been synthesized by Moore and Miller.² The experimental determination of the value of succinylsulfathiazole as an intestinal antiseptic and its early clinical use were described by Poth, Knotts, Lee, Inui, Chenoweth and Welch, Mattis and Latven.³ The drug has been used for about one year and has been given to approximately 250 patients in this clinic. These cases have been studied closely for evidences of hemocytologic changes and accumulation of the drug in the blood. The total quantity of drug excreted in the urine was determined in the majority of these cases and the alteration of the intestinal flora was assayed by quantitative bacteriologic study. Within one to seven days of the institution of sulfasuxidine therapy the feces became semisolid, small in bulk, somewhat gelatinous in appearance and relatively odorless.

When these changes occur, the bacterial flora of the bowel will have been considerably altered. The *Escherichia coli* count will have dropped from an aver-

age of ten million to less than a thousand organisms per gram of wet stool. Frequently *Escherichia coli* is not recovered on poured plates when one uses desoxycholate medium containing a minimum of 1 mg of para-aminobenzoic acid per hundred cubic centimeters of the medium to inhibit the action of the drug.

ALTERATION OF THE BACTERIAL FLORA OF THE GASTROINTESTINAL TRACT BY THE LOCAL ACTION OF SUCCINYL-SULFATHIAZOLE

The coliform bacterial population of feces normally varies between one million and one hundred million per gram of wet stools. The number of the gram negative and gram positive flora is roughly equal and usually varies from one hundred million to ten thousand million organisms per gram of wet feces. When succinylsulfathiazole is administered in effective therapeutic doses the gram positive and gram negative organisms decrease in number at approximately the same logarithmic rate for a few days until the gram positive population becomes constant. The number of gram negative bacteria continues to fall. The latter decrease is not due solely to the change in the number of coliform organisms (chart 1). The bacteriologic identification of the different organisms making up these groups has not been practical because of the many different varieties of bacteria involved.

That this drug has bactericidal as well as bacteriostatic action against *Escherichia coli* is demonstrated by the introduction of this compound into surgically prepared isolated loops of large bowel. Dogs will tolerate isolated loops of the large bowel and will survive indefinitely. If succinylsulfathiazole is introduced into such an isolated segment the coliform organisms will decrease strikingly and may disappear completely (chart 2). Obviously the living organisms cannot escape from the isolated segment and their disappearance is due either to the lethal activity of the drug or to the natural death of cells without subdivision to give new generations of organisms.

ROUTINE PREOPERATIVE PREPARATION

During the past six months the following regimen has been instituted for the preoperative preparation of all patients whose intestine is not completely obstructed and requiring operations on the large bowel. The patient is put on a low residue diet and receives succinylsulfathiazole. A dosage of 0.5 Gm per kilogram of body weight is given during the first day and thereafter 0.25 Gm per kilogram daily divided into six equal doses and administered at four hour intervals. No enemas or purgatives are used. Ordinarily in the course of three to seven days the stools will become small in bulk, semisolid and relatively odorless. A bacteriologic examination of the feces will show the bacterial flora to be significantly altered. By now the patient's abdomen is flat and the bowel is free from gross fecal material and gas.

Experience has demonstrated that when the *Escherichia coli* count has dropped to one thousand and the other significant alterations in the feces have taken place the bowel is properly prepared for operation. A simplified technic has been devised to estimate when the coliform bacteria have been reduced to one thousand organisms or less per gram of wet feces.

A small quantity of fecal material is triturated with a drop of sterile water containing 5 mg per hundred cubic centimeters of para-aminobenzoic acid. A 2 mm platinum loop is filled with the triturate and streaked

This study was aided by a grant from Sharp and Dohme of Philadelphia.

on a desoxycholate agar plate Roughly 0.01 Gm of feces will be transferred and streaked on the plate Therefore, a colony count of one hundred would indicate approximately ten thousand coliform organisms per gram of wet stool When the count on the streaked plate is less than ten colonies, the *Escherichia coli* con-

operation, have received preoperative and postoperative treatment with succinylsulfathiazole In no instance has it been necessary to discontinue the drug therapy because of untoward reactions

Table 1 indicates the pathologic lesions found in these patients and table 2 lists the operations performed

These patients, 50 in number received the drug preoperatively until the stools were semifluid, small in bulk and relatively odorless and the coliform bacteria were reduced to one thousand or less per gram of wet feces Succinylsulfathiazole was administered postoperatively as soon as the patient tolerated 30 cc of warm water by mouth and was continued as long as twelve days in those instances in which primary suture of the bowel had been done

The postoperative course of these patients as a group was unusually smooth Some of the patients had moderate gaseous distention, but troublesome, extensive abdominal distention did not occur, and gas pains were ordinarily mild and of short duration Although many of the intestinal anastomoses were performed by the open technic, postoperative peritonitis and deep abscess

TABLE 1—Patients Grouped According to Condition

Condition	Patients
Carcinoma of right colon	7
Carcinoma of transverse colon	3
Carcinoma of left colon	26
Fecal fistulas involving colon	6
Chronic volvulus sigmoid	1
Diverticulitis of colon	2
Lesions of urinary bladder (transplantation of ureters into bowel)	3
Rectovesical fistula	2
Total	50

tent of the feces would be less than one thousand Obviously this procedure is not quantitatively accurate, but it is sufficiently accurate to indicate when the bacterial flora of the intestinal tract has been significantly altered and it serves as a simple practical means of determining when operation can be undertaken (chart 3) *Aerobacter aerogenes* grows on desoxycholate medium to produce a gelatinous colony with a red center and must be differentiated from *Escherichia coli*

If, however, distention continues, the feces do not change their physical characteristics and the bacterial flora is not altered, the bowel is not properly prepared for operation The usual causes for failure are intractable diarrhea and the administration of liquid petrolatum The diarrhea can usually be controlled with opiates, and liquid petrolatum should be withheld Attention is directed to the fact that opiates given to control a severe diarrhea will not cause an accumulation of fecal material while the patient is on a low residue diet and is receiving therapeutic doses of succinylsulfathiazole This regimen of preoperative treatment has always resulted in a clean bowel, and it has not been necessary to abandon a planned operative procedure because of an unsatisfactorily prepared colon The recent experience in this clinic indicates that if the bowel can be freed of fecal material by the use of purgatives and enemas it can be cleansed equally well by merely

Chart 1—Alteration of the bacterial flora in the bowel following the administration of succinylsulfathiazole Before therapy is begun in this instance the total gram positive and gram negative organisms each number approximately 10^{11} and the *Escherichia coli* number about 10^8 Thus the total gram negative organisms initially exceed the number of *Escherichia coli* by practically 10^{11} while after fifteen days of treatment the difference is roughly a thousand Also the total gram positive organisms surviving after therapy are only one millionth of their initial number

TABLE 2—Operative Procedures Involving the Large Bowel and Performed on Patients Receiving Preoperative and Postoperative Treatment with Succinyl Sulfathiazole

Operation	Number of Cases
Abdominal-perineal resection (Miles)	16
Resection of sigmoid primary anastomosis	14
Resection carcinoma of transverse colon primary anastomosis	3
Resection of cecum ascending colon ileocolostomy	7
Resection of fecal fistula	6
Ureterosigmoidostomy	3
Repair of rectovaginal fistula	1

formation did not occur with one possible exception, when following the second stage of a difficult uretero-sigmoidostomy extravasated urine collected in the pelvis and required drainage It is interesting to note that a culture of this extravasated material gave the alpha *Streptococcus fecalis*, *Escherichia coli* was absent

No postoperative fecal fistulas have developed An occasional superficial wound infection has occurred The length of the patient's stay in the hospital certainly has not been prolonged by succinylsulfathiazole therapy

QUANTITATIVE STUDIES ON SUCCINYL-SULFATHIAZOLE THERAPY

The estimation of total urinary excretion of the drug by more than 200 patients has shown an average of less than 5 per cent of the ingested compound in the urine Crystals of succinylsulfathiazole are not present in freshly voided urine Quantitative bacteriologic studies of the feces of these patients show less than one thousand *Escherichia coli* organisms per gram of wet feces after the following periods of treatment (chart 4) (1) 38 per cent within three days of ther-

administering succinylsulfathiazole This regimen has the advantage of causing no dehydration of the patient just prior to operation as well as removing the bulk of pathogenic bacteria

OPERATIVE TREATMENT OF LESIONS INVOLVING THE LARGE BOWEL

In this clinic during the past year all ward patients requiring operations involving the large bowel, excepting those with acute conditions demanding immediate

typy (2) 79 per cent within five days of therapy and (3) 93 per cent within seven days of therapy

The remaining 7 per cent of the patients in this series who did not respond within seven days of treatment to effect a significant alteration of the intestinal flora usually presented some special condition which

Chart 2—Action of succinyl sulfathiazole in an isolated loop of the descending colon of the dog. Five Gm of succinylsulfathiazole introduced into the segment of bowel at the time of operation reduced the number of coliform organisms to zero in two weeks and could not be recovered again during the course of the experiment. Solid drug was always present in the loop to indicate that the drug is slowly absorbed from the colon

interferes with the action of the drug, such as the presence of a blind or short circuited loop of bowel into which the drug cannot be introduced the persistence of a severe uncontrollable watery diarrhea or the occurrence of a degree of obstruction which does not allow sufficient evacuation of accumulated fecal material

At some time during the course of adequate treatment 95 per cent of the patients have less than one thousand *Escherichia coli* organisms per gram of wet feces, 59 per cent less than one hundred and 37 per cent less than ten

Chart 3—The use of a platinum loop which will transfer approximately 0.01 Gm of fecal matter to streak a desoxycholate agar plate is sufficiently accurate to indicate when the bacterial flora has been significantly altered. Example: When the coliform count has been reduced to one thousand the colony count on the streaked plate will vary from five to fifteen

The quantitative estimation of the concentration of the sulfonamides in the whole blood shows the free drug present at levels between 0.5 and 1.5 mg per hundred cubic centimeters whereas the conjugated derivatives vary between the levels of 1.0 and 2.5 mg per hundred cubic centimeters

TOXICITY OF SUCCINYL-SULFATHIAZOLE

Toxic reactions coincident with the administration of succinylsulfathiazole are infrequent and mild. An occasional individual may complain of dizziness, headache or loss of appetite. Hematuria, hemocytologic changes and crystals of the drug in the urine have not been observed. With a single exception hyperpyrexia, vomiting and erythema have not occurred. One individual in this series of 250 persons receiving succinylsulfathiazole had a moderately severe reaction to the drug. This patient, a woman suffering an acute exacerbation of a long-standing chronic ulcerative colitis complained of headache, nausea, vomiting, chills and fever, and pain in her joints after receiving 0.25 Gm of succinylsulfathiazole daily for eight days. On admission to the hospital the patient's temperature was 103 F. Lesions similar to erythema nodosum were present on the anterior surfaces of both legs, moist rales were heard on the right side of the chest, drug levels in the blood were not elevated, the blood count was normal except for a 5 per cent eosinophilia and the urine was normal. There had been no urinary manifestations of drug intoxication. A week later, when all evidence

of the reaction had subsided the patient was given a single dose of 1 Gm of sulfathiazole. Within five hours after the administration of the sulfathiazole the patient's temperature had risen to 103.6 F, the leukocyte count had changed from 10,000 to 36,000, rales reappeared throughout both lung fields, the patient complained of joint pains and headache, and the site of the original skin lesions showed a slight erythema. These toxic manifestations subsided in thirty-six hours. Obviously this patient is highly sensitive to sulfathiazole, and because of the hydrolysis of succinylsulfathiazole to yield sulfathiazole in small amounts, drug reactions must be expected in such susceptible individuals, who, fortunately, are few in number. It should, however, be emphasized again that any patient receiving succinylsulfathiazole should be under observation especially if the drug must be given over long periods, as has been done in the treatment of chronic ulcerative colitis.

Chart 4—Length of succinylsulfathiazole therapy required to effect a significant alteration of the bacterial flora in the bowel. The 7 per cent of cases requiring more than seven days include those cases which present special circumstances unfavorable to the action of the drug as well as those instances which fail to give a satisfactory response

COMMENT

A dogmatic evaluation of the benefit resulting from the administration of a drug such as succinylsulfathiazole in the preoperative preparation and postoperative therapy of patients subjected to operative procedures on the large bowel cannot be made after only one year of use in a series of 50 cases. This study does, however, indicate that the postoperative course is unusually smooth, that serious complications due to infection following fecal contamination are largely eliminated and that the period of hospitalization and convalescence is definitely shortened.

The toxicity of the drug is so slight that its administration has added no new hazard. There has been no evidence of kidney damage. Because of the low toxicity

and the slight degree to which the drug is absorbed, a further simplified practical regimen for the administration of succinylsulfathiazole is proposed. The preoperative therapy does not require hospitalization. Since the stools become small in bulk and semifluid, it is unnecessary to use purgation and enemas for cleansing the bowel of gross fecal material. The elimination of purgation during the preoperative period decreases the tendency toward dehydration and brings the patient to operation in much better condition.

The length of preoperative preparation is determined by the appearance and odor of the feces and by the relative number of coliform bacteria present as determined by the streak-plate technique described. Routine determination of the concentration of the drug in the blood is not essential and might well be reversed for occasional observation when indicated because of possible untoward reactions. By following this procedure in the administration of succinylsulfathiazole the length of stay in the hospital could be significantly reduced. Extensive laboratory procedures also are unnecessary.

While too much importance should not be attached to the mortality rate in this small series, it is interesting that no deaths occurred following primary suture of the large bowel in the 30 cases included in this study. In no instance was a proximal enterostomy performed. Two deaths have occurred following abdominal-perineal resection of the rectum. In one instance the blood supply to the distal 6 inches of the descending colon was insufficient with resulting necrosis of this segment of bowel. In the second case anuria developed postoperatively, and at autopsy both ureters were found to be mechanically blocked by a large perineal pack. I have learned of a third death following the use of succinylsulfathiazole in another hospital not included in this series. The patient, a woman aged 72, died quite unexpectedly on the ninth postoperative day following a primary anastomosis and resection of the sigmoid for carcinoma. The attending surgeon considered that death was due to embolism. An autopsy was not obtained.

The postoperative administration of succinylsulfathiazole may not be necessary, and a comparative study should be made to determine whether or not patients will be as free of gas pains and distention without the administration of the drug after operation.

As soon as one is convinced that this drug is a useful adjuvant in surgery of the large bowel, one should consider the advisability of employing others of the sulfonamides simultaneously for their general effect and as local agents to be employed where extensive contamination has occurred.

ABSTRACT OF DISCUSSION

DR JOHN S. LOCKWOOD, Wynnewood, Pa. We started in 1938 to use sulfanilamide routinely at the Hospital of the University of Pennsylvania in all cases of intestinal resections and anastomoses. Dr. John Garlock independently adopted the same practice and published a preliminary report in May 1939. The series of Dr. I. S. Ravdin and my other colleagues in Philadelphia exceeds 120 consecutive cases with no instances of postoperative peritonitis. During the past two years we have made free use of local application of 5 to 8 Gm. of crystalline sulfanilamide to the operative site. In spite of occasional instances of drug fever, anemia and jaundice resulting from this practice, we believe that our end results have amply justified its use. We have administered succinyl sulfathiazole to a number of patients and have made bacteriologic and pharmacologic studies on them. In the great majority of the cases there was a drop in the number of coliform bacteria to less than

10,000 per gram of stool, but the period required for achieving maximal reduction was five to seven days. Furthermore, we have studied the action of the drug on *Clostridium welchii* and the *Streptococcus fecalis* group. We found that the drop in the number of clostridia parallels rather closely the drop in the number of coliform bacteria, except that it takes a little longer, probably six to eight days, for the reduction in the number of clostridia to take place. Recognizing the probable importance of certain types of bacterial synergism in peritonitis, it is probably significant that both the coliform and the *Clostridium* group are susceptible in the fecal stream to the action of this drug. In all our cases there was an increase in the total number of streptococci. The highest blood level of sulfathiazole in any of our cases was 1 mg. per hundred cubic centimeters of free drug and 1.3 mg. per hundred cubic centimeters of its conjugated derivative. This indicates the striking degree to which this drug is held in the intestinal lumen. In our cases an average of about 3 per cent of the total amount of the drug administered was excreted in the urine, the remainder coming out in the feces. The concentrations of free sulfathiazole in the feces ranged from 85 to 200 mg. per hundred cubic centimeters; a concentration certainly capable of exercising a profound bacteriostatic effect. It seems that the presence of the succinic grouping tends to prevent absorption of the sulfathiazole in the small bowel. By the time free sulfathiazole becomes liberated through hydrolysis the drug has reached the lower bowel, where absorption of sulfathiazole is definitely limited and the active drug remains in the lumen in sufficient concentrations to produce its desired effect. We have administered the drug in the dosages recommended by Dr. Poth, about 0.25 Gm. per kilogram daily with an initial dose of that amount, the daily dose being divided into six fractions administered at four hour intervals. Our experience has not yet been carried to a point of determining the extent to which this drug will help in further improving the end results of bowel surgery. However our data completely confirm the work of Dr. Poth and his co-laborators. At the same time we shall not fail to recognize that sulfonamide prophylaxis and therapy is never to be used as a substitute for good judgment in selection of case, for good surgical technique and for adequate employment of other measures of preoperative and postoperative care of recognized value.

DR H. C. SALTZSTEIN, Detroit. Seven dogs were given succinylsulfathiazole orally for seven days before the operation and ten days after it. The dose was $\frac{1}{3}$ Gm. per kilogram initial dose, and the same dose in twenty-four hours in three divided doses. At the end of the preliminary period of seven days the abdomen was opened, a large incision was made in the descending bowel, perhaps fully one third of the way across; the bowel was dropped back and the abdomen was closed. This repeated one of Dr. Poth's experiments. Of these 7 dogs, 2 died within twenty-four or forty-eight hours of the operation and there was some evidence of healing in each. The other 5 convalesced normally and apparently the procedure disturbed them not a bit, there was no evidence of distention, abdominal irritation or nausea. In 5 control dogs in which the bowel was opened and dropped back, no drug was given. All died in less than twenty-four hours of apparently a very virulent peritonitis. The few times we have used this drug in man we can confirm that the blood level rarely goes above 1, there was perhaps 5 per cent excreted in the urine, and it was tolerated very well. Taking several pills did not upset the stomach except in a few instances. A surviving dog was opened again thirty-three days after the operation. There was an adhesion at the site of the injury to the bowel, and no other lesions anywhere in the abdominal cavity. As this was dissected off, there was found a rather clean serosal surface which one can hardly recognize as having been an incision directly into the bowel itself.

DR EDGAR J. POTII, Baltimore. Dr. Lockwood's quantitative studies of the antibacterial action of succinylsulfathiazole for clostridia support our supposition that various anaerobic organisms are affected. The decrease of the fecal odor of the contents of the large bowel has led me to feel that the so-called bacteroids are likewise susceptible to the bacteriostatic action of the drug. Dr. Saltzstein's film is a rather convincing bit of

evidence that succinyl sulfadiazole has antibacterial properties. I hope this demonstration will not invite overconfidence, but these observations on the protection against peritonitis afforded when the drug is administered in adequate amounts justifies the giving of this drug during the immediate postoperative period especially when a primary suture of the large bowel has been performed. Because of the rapidity with which *Escherichia coli* reappears in the feces on withdrawal of sulfadiazine the oral administration of the drug should begin as soon as possible after operation. When the patient will tolerate 30 cc of warm water by mouth which is usually within the first twenty-four hours the administration of the drug can be started again. Surprisingly the patients will take several large 0.5 Gm tablets every four hours without vomiting. Because of the low toxicity of the drug and since the use of enemas is ordinarily not necessary it is not imperative that the patient be hospitalized during the period of preoperative preparation.

THE CONDITIONED REFLEX TREATMENT OF CHRONIC ALCOHOLISM

VIII A REVIEW OF SIX YEARS' EXPERIENCE WITH THIS TREATMENT OF 15% PATIENTS

FREDERICK LLMERE, MD
WALTER L. VOEGTLIN, MD
WILLIAM R. BROZ, MD
PAUL O'HOLLAREN, MD
AND
WARREN F. TUPPER, MD
SEATTLE

There is no disease in the whole field of medicine that brings as much grief to the patient and his family as alcoholism. Judging from the literature¹ the usual therapy including amphetamine vitamins, sedation hospitalization and psychotherapy is woefully inadequate.

The only reliable report of the results of treatment in the entire medical literature shows not more than 15 per cent of 124 patients still abstinent at the end of eighteen months.² Some alcoholic addicts are cured by religion³ and a few undoubtedly cure themselves.

Our observations indicate that the therapy to be described in this paper is definitely superior to any previously used for the treatment of alcoholism.

ETIOLOGY OF ALCOHOLISM

The uninitiated think of alcoholism simply as a weakness of will power. The psychiatrist thinks of excessive drinking as a neurosis but the usual treatment for neurosis is seldom effective. Aside from being somewhat temperamental, most of our patients have become quite normal when not drinking.

We feel that excessive drinking is a disease in that the patient has an abnormal reaction to alcohol not shared by the normal drinker. As soon as alcohol starts circulating in the blood of the alcoholic addict there develops a change in personality and judgment not found in the controlled drinker.

The basis for this intolerance to alcohol is not known but an inherited constitutional predisposition is often

present. We have found excessive drinking in the family background of the alcoholic addict four times as frequently as in the normal drinker. Other patients develop an idiosyncrasy to alcohol after years of heavy drinking. There is undoubtedly a psychogenic basis for drinking in many cases, but investigation of these factors rarely seems to help the patient to stop his drinking.

THE CONDITIONED REFLEX TREATMENT OF CHRONIC ALCOHOLISM

There is no known treatment for a patient who does not want to stop drinking except to help him sober up between bouts. When a patient finally does decide to stop drinking he often finds it impossible to break the habit without some outside help. The object of the conditioned reflex treatment is to give the patient this help.

The conditioned reflex treatment of alcoholism was first described by Voegtlin⁴ in 1940. The detailed technique of this treatment will be published elsewhere.⁵ It consists essentially in establishing a reflex aversion to the sight, smell, taste and thought of alcoholic beverages by means of emetine. The emetine produces prompt emesis of imbibed alcoholic beverages, which are urged on the patient for thirty to forty-five minutes after the administration of the emetine. Anywhere from four to eight of these treatments are given over a period of a week to ten days, at the end of which time most patients will have a strong aversion to liquor of any kind.

This reflex aversion is periodically reinforced by giving one or two treatments at intervals of one to three months throughout the first year, when relapses are most apt to occur.⁶

If possible, this treatment should be given in a hospital devoted solely to alcoholism. The fellowship of the patients and their frank discussion of their problem among themselves and with the staff are valuable adjuncts to the treatment. It is impressed on the patient that the first drink is the dangerous one. He is taught that alcohol does not agree with him and he must leave it completely alone.

RESULTS OF TREATMENT

To date we have made no attempt to select patients. Unfortunately we have no absolute criteria on which to base prognosis. Some apparently hopeless ones have been our best patients. If we could exclude the constitutional psychopathic, the inadequate and the highly nervous types of patients, our results would be better. The problem is usually so desperate, however that we have not felt justified in refusing treatment to any patient who comes to us for help.

Although most of our patients come for treatment of their own accord, some come under duress of their family, their employer or the courts. These patients do almost as well as the purely voluntary patients provided they see the light and have a change of heart after starting treatment.

Out of 1,526 patients treated we have been able to obtain accurate follow-up reports on 1,194. Of 644 patients treated within the last two years 74.8 per cent

are still abstinent, of 291 patients treated from two to four years ago 52.5 per cent are still abstinent and of 259 patients treated four or more years ago⁷ 51.5 per cent are still abstinent. We have not included as relapses those patients who attempted to drink but became ill and quit immediately for the treatment served its purpose of keeping these patients from drinking.

Patients under 30 years of age, professional men (including doctors) and women were especially difficult to treat, as drinking in these patients represents a more severe break with normalcy than in the average patient.

Ninety-nine persons were released without treatment, owing to the fact that they refused therapy. These patients were reluctant to admit that their drinking was a problem or were unwilling to live a life of total abstinence.

Relapses are dangerous for retreatment is effective in only about 25 per cent of these patients.

COMMENT

The advantages of this treatment lie in its short duration, its wide applicability and its ready acceptance by the patient. One cannot help but comment on the excellent morale and cooperation shown by our patients. Even those patients who had relapsed were still friendly toward the sanatorium. They rationalized their relapse usually as a curiosity as to how liquor would affect them after taking the treatment, or a hope that they could now drink moderately. The evidence for the necessity of total and permanent abstinence is so conclusive that we must insist that the patient give up any idea of even attempting to drink again. Many of the patients who relapsed headed back to the sanatorium of their own accord for further treatment.

Although we have not attempted any psychotherapy we feel that there is a definite place for a rehabilitation program in conjunction with this treatment. In districts where the field representatives (usually ex-patients with special training) kept in close touch with the patient and assisted him in getting straightened out with his family and his job, the results were substantially better than in those areas where this was not done. A close personal contact with the patient is essential and that is why we do not believe that this treatment should be given in public institutions.

A frequent question concerning this treatment is why the vomiting that so many alcoholic patients go through does not establish a natural aversion to liquor. The answer is that by the time the vomiting occurs the patient is foggy mentally and does not care much what happens to him. In order to establish a conditioned reflex the patient's mind must be clear.

SUMMARY

1 The conditioned reflex method of treating alcoholism attempts to establish, by means of emetine, a reflex aversion to the sight, smell, taste and thought of alcoholic beverages.

2 Out of 1,194 patients followed up, 74.8 per cent of 644 patients treated within the last two years are still abstinent, 52.5 per cent of 291 patients treated from two to four years ago are still abstinent and 51.5

per cent of 259 patients treated four or more years ago are still abstinent.

3 The advantages of this treatment lie in its short duration, its wide applicability and its ready acceptance by patients who really want to stop drinking.

CONCLUSION

We believe that this is the best available treatment for alcoholism.

706 Medical and Dental Building

ABSTRACT OF DISCUSSION

DR. JOSEPH THIMMANN, Boston: I have applied the technique on 37 patients in the Washington Hospital and the Peter Bent Brigham Hospital in Boston. Up to the present time 30 of the 37 patients are totally abstinent for a period longer than ever before in their drinking careers. The material was heterogeneous as a number were social agency patients. This is not irrelevant. In these patients the work history was mostly poor. There was often no trade at all. The fact that the fee was paid by the agency and not by the patient developed in the patient's subconscious mind possibly an attitude comparable to that of a spoiled child. That person will probably not value much what is done for him. He may even display a kind of hostility toward it in order to reduce the feeling of indebtedness. A patient with that kind of personality and attitude would rather be expected to give only half hearted cooperation or even negativism that will make him plan, as soon as the treatment is over to prove that the therapist was as unsuccessful as the patient himself in his previous attempts. This type of patient will do it with even less inhibition, as the strenuous and unpleasant treatment will gratify not only his possible masochistic traits but also reduce his feeling of guilt. With this in mind, it will be not too surprising that of seven failures five were such social agency patients. The opposite extreme in this group of not very promising patients will be the spoiled child type of patient from wealthy environment. I am thinking of 1 to whom his mother had to promise \$50,000 in order to make him agree to the treatment. An interesting pattern of failure was a patient who, after having been conditioned, feeling unable to drink, took large amounts of second and only in this condition practically drunk from that drug, was able to take some drinks. This mechanism makes me wonder whether barbiturates could not be included in conditioning as if they were another kind of drink. Two of those who relapsed have stated that their definite abhorrence for drinks and feeling of security was rather reduced by the reinforcement one month after the main series. Is it possible that in some cases the one session reinforcement would rather weaken the conditioned reflex? We do not see in the reports of any other method of treatment of alcoholic addicts such definite, long term results as shown by the conditioning treatment, nor do we know of such a systematic and long follow-up as Dr. Lemere and his associates have given their patients for four and five and one half years.

DR. JAMES P. KING, Radford, Va.: Of the 105 patients with chronic alcoholism treated at Saint Albans Sanatorium from May 1941 to May 1942, only 8 elected to take the alcohol conditioning reflex treatment. No effort was made to induce these patients to take this treatment. Each was told of its possibilities. One patient under treatment stated "This procedure reminds me of the way you house break a dog." On the whole, the alcoholic patients whom we have seen have not been receptive to the idea. Many alcoholic addicts do not desire to be relieved of their ability to drink. Those who sincerely wish to be cured are loath to subject themselves to the rather strenuous process of conditioning. Of the 8 patients treated by the method outlined by Dr. Lemere and his co-workers 5 were considered as successfully conditioned against alcohol. Of these, 1 relapsed after nine months of total abstinence. However, when returning to the hospital he stated that the aversion to alcohol decreased rapidly after the third month and, should the present method of reinforcement have been employed in his case, it is presumable that the relapse would not have occurred. Of the 4 remaining patients successfully conditioned, 1 relapsed after three months, 3 have been totally abstinent for three, six and

⁷ We have not attempted to follow patients much beyond four years as the reports become undependable and it is hard to obtain accurate information.

ten months respectively. It is noteworthy that each of these patients was an alcoholic of long standing and had received treatment by other methods in our hospital or elsewhere. I am of the opinion that more emphasis should be laid on the value of the treatment to the patient and, while he should be permitted to make the final decision, added effort should be made to increase the number of the patients treated. As 7 of our patients did not receive the advantage of reinforcement, it is likely that the number of cures would have been greater had this method been employed. I believe that the conditioned reflex treatment combined with the proper psychotherapy is a valuable method of treatment of the chronic alcoholic patient. I should like to ask Dr. Lemeré what happens to these patients if they are successful in the treatment. I should like to know whether they develop neuroses or psychoses or how they adjust themselves to life without alcohol.

DR ROBERT V. SPICER, Baltimore. I do not feel, as the authors do, that alcoholism is a disease in every case but rather that in most cases it is a symptom of some underlying illness, usually emotional, psychologic or psychogenic. We know that many people stop by themselves. Religious conversion has helped many. The Alcoholics Anonymous in this country are helping many. And we still help many by conventional psychotherapeutic measures. The aversion treatment is nothing, especially new. Dent in London worked along this line for years. I should like to ask the authors whether or not theirs is a sort of streamlined Keeley cure. An important factor in treatment is the individual's strong and sincere desire for help. There are various types of alcoholic addicts. Among these types are the bad egg alcoholic addicts—the 100 per cent total psychopaths whom nobody can help the neurotic alcoholic, the psychotic alcoholic, the situational alcoholic, the maladjusted alcoholic and the feebleminded alcoholic. I should like to ask whether some patients, either consciously or subconsciously, have not responded to the psychologic implications of the treatments being administered in a sanatorium and therefore necessarily provoking some new nondrinking thought and habit associations. Do the authors use no psychotherapy at all? If so, did none of their numerous patients use alcohol as an escape or to remove frustration? Psychiatrists interested in the subject feel that some of the alcohol problems give evidence of a neurosis or psychosis, how have these types reacted without the use of alcohol on the one hand or of reorienting and guiding therapy on the other? The psychiatric approach to alcohol problems involves deep probing into the mechanism and other factors of the neurotic and psychotic alcoholic addicts. There is no infallible specific cure for patients with alcohol problems. In the final analysis this problem always represents the psychobiologic reaction of an individual personality to life and life situations, plus habit formation with respect to emotional reactions and to the use of a drug. We should therefore remember that psychotherapy must be considered at least as a possibly useful approach for many alcohol problem patients.

DR FREDERICK LEMERÉ, Seattle. In our group there is a certain natural selection. Most of the patients come of their own accord and they are responsible individuals. Most of them are business men or defense workers, people who make normal adjustment when they aren't drinking. Therefore we get a better type of patient to treat, and that probably accounts for some of our results. About 70 per cent of our patients now are defense workers. It is very important to get them to stop drinking. At one airplane factory 50 per cent of the men that they lose are lost through alcoholism. Dr. Thimann said something about a question as to the value of reinforcement. It does put a doubt into the minds of some patients as to the effectiveness of the treatment, but on the whole it should be rational to reinforce them throughout the year's time. I think we save more than we lose by that procedure. The technique of the treatment is new, and there are unlimited variations that could be developed such as elimination, probably, of the pilocarpine. When we use salt water to put the oral emetine in, some of the patients have objected to that, so we are now trying the emetine in capsules before the treatment. Dr. King stressed the importance of the patient's cooperation. That is very important, because unless the patient wants to stop drink-

ing nobody is going to help him. The question was brought up as to what happens to the patients after they stop drinking. A couple of students came up to me yesterday after the movie and said "We were taught in medical school that if a patient stops drinking then he goes into other forms of abnormal activity, like morphine addiction, barbiturate addiction or criminal behavior." We haven't found that true at all. We find them, if they aren't drinking, to be fairly normal and responsible and successful in their community, at least the type we are getting or else they go back to drinking. The actual figures show that 5 patients went to state hospitals several months or a few years after treatment. None of them went into morphine addiction, 3 went into addiction of barbiturate and none into criminal activity. Dr. Seliger's emphasis on the psychogenic aspects is important. We haven't had opportunity to go extensively into this part of the treatment, but we feel that we get just about as good results without. Most of the patients don't like to go into their personal problems too much, and, if they do, they seem to delight in telling about them and it doesn't seem to help particularly. This treatment has no relation to the Keeley cure, which used gold chloride and was a secret formula treatment. The best criterion will be the reports of actual results of the different types of treatment. There is no reason why the exact figures shouldn't be reported.

AMBULATORY TREATMENT OF CHRONIC ALCOHOLISM

A CLINICAL STUDY

MICHAEL M. MILLER, M.D.

Assistant Surgeon Reserve

LIVINGTON, KY

The treatment of chronic alcoholism has long been regarded as unsatisfactory. As far as can be determined from the literature, therapeutic measures have heretofore embraced only certain phases of the problem and there has been no adequate unified approach toward the various problems confronted in treatment. Some of the principal attempts that have been made in dealing with this disorder are the socioreligious approach of the Alcoholics Anonymous, psychoanalytic treatment, the conditioned reflex technique, the religious appeal to will power and faith and the punitive approach of the courts as well as the many attempts to use medication in the treatment of this disease by the medical profession.

Abstinent groups, such as Alcoholics Anonymous, recognize the great value of engaging the alcoholic addict actively in the social activities of a nondrinking environment and of offering him more constructive ways of employing his vocational ability and leisure time, using mutual understanding and past experience to good advantage.

As for the psychoanalytic approach to this problem, it presents a number of difficulties. First, it does not always provide adequately for the physical and social rehabilitation of the patient. Furthermore, it usually requires a great deal of time of both patient and psychoanalyst to yield good results, thereby becoming a costly and impractical method for large scale treatment. Its use is also limited to certain types of patients.

The conditioned reflex treatment involves various combinations of suggestive therapy in order to condition

From the United States Public Health Service Hospital.

This work was supported by grants from the Smith Kline & French Laboratories.

Mr. William E. Kirsch and Mr. Theodore Wallace of the Research Department of the Smith Kline & French Laboratories, Philadelphia, supplied the medication used in the experiment.

Dr. Fritz Glaser, formerly of the Wagner Jauregg Clinic, Vienna, Austria, gave advice and assistance in the psychotherapeutic handling of many of these cases. Dr. Ralph R. Brown, Research Psychologist of the United States Public Health Service Hospital, gave invaluable assistance in the presentation of the material. Drs. Lawrence Kolb, John D. Reichard and Michael J. Pescor of the United States Public Health Service offered constructive criticisms.

the patient to a fear and dislike of alcohol by the simultaneous administration of liquor and a strongly emetic drug, such as apomorphine, which can produce extreme nausea and vomiting. This method, unfortunately, frequently ignores the existing psychic and social factors. Such treatment is disagreeable and may be dangerous. The late Francis Dercum¹ stated that "the use of apomorphine or of other nauseant drugs in the treatment of alcoholism is unscientific and is to be strongly deprecated." It can readily be seen that no constructive social and psychotherapeutic program for the patient's future is provided in this treatment.

The religious appeal to will power and faith by persuading the alcoholic addict to take a pledge also fails to recognize sufficiently the existence of psychosocial maladjustment and to deal with it scientifically. Certain devout persons, no doubt, have been benefited by taking the pledge but others with more deep-rooted psychologic and social conflicts may have been harmed by the development of a sense of increased inadequacy and guilt.

Courts differ somewhat in their attitude toward this problem but, in general, it is assumed that drunkenness is a crime against society rather than a disease and should be punished by fines and incarceration.²

A number of authorities, including Asst Surg Gen Lawrence Kolb³ of the United States Public Health Service, have pointed to the harm done in many municipalities through the mishandling of the problem by the police authorities. Certainly incarceration fails to provide for the psychosocial readjustment of the patient. Patients turn, generally, toward an antisocial rather than to a social adjustment under such conditions. Incarceration usually fails to develop a sense of responsibility and adequacy in the patient. On the contrary, it frequently induces apathy, hopelessness and demoralization. Furthermore, it frequently harms the family and in many instances, destroys its unity. Frequently severe economic hardships have been imposed on the individual, such as the accumulation of debts as well as loss of job and income. Judging from the large number of offenders who have been rearrested, the results of such treatment can be regarded as poor.

A specific medical approach alone can be of little permanent value, since it too does not provide for the psychologic and social adjustment of the patient. Medication cannot be ethically administered for an indefinite period if other measures are possible. For in many instances the patient becomes increasingly dependent on the drug for support instead of developing the very necessary qualities of adequacy and responsibility. Certain drugs, however, can be beneficial in chronic alcoholism if used judiciously as adjuncts to psychotherapeutic and social treatment.

Although the literature dealing with the problems of treatment in the field of alcoholism is voluminous, the relative values of various treatments are difficult to determine because of the fact that workers in this field frequently fail to incorporate control studies in their clinical procedures. Without information concerning the number of relapses to be expected in untreated groups, it is difficult to determine the extent to which any particular treatment was effective. For

example, Reifstein and Davidoff⁴ found that some improvement was accomplished in only about 10 per cent of their cases in which amphetamine sulfate was employed as a pharmacologic aid. Bloomberg,⁵ on the other hand, reports that 66 per cent of his alcoholic patients remained abstinent for periods ranging from six months to more than a year mainly because of the use of amphetamine sulfate. In a more recent report⁶ he states that out of 55 patients treated with amphetamine sulfate and psychotherapy over periods ranging from a few weeks to three and three-quarters years, 25 per cent remained totally abstinent and another 60 per cent had undergone beneficial modification of their drinking habits. He noted that the "hangover" and depression were relieved. In a still more recent report on 56 patients⁷ treated with amphetamine sulfate and observed for periods ranging from several months to more than three and one-half years, Bloomberg states that 22 patients have been totally abstinent to date, 34 have had a relapse, 15 of these showing definite improvement as a result of treatment. He lists 8 patients as total failures in treatment. (Bloomberg used amphetamine sulfate in all cases and psychotherapy as well in about half, apparently because he felt it was indicated.) None of these authors attempted to determine the extent of abstinence which would be observed in untreated groups of the same economic status.

The great majority of workers in the field of alcoholism tend to ignore the need for adequate definition of terms in connection with the material with which they are dealing. The problem as to what constitutes an alcoholic patient has not been satisfactorily answered, and criteria for relapse have been neglected. It is well recognized that such criteria are difficult to define with any degree of accuracy but unless adequate definitions of criteria are employed the results cannot satisfactorily be evaluated.

The term chronic alcoholism as used in this paper refers to the use of alcohol by an individual to the extent that it becomes a medical or social problem to him or to society.

In the present paper an attempt has been made to evaluate the effects of a treatment for chronic alcoholism which is based on a three point program consisting of (1) medical treatment, (2) psychotherapy and (3) social reorientation and rehabilitation. The rationale of this three point program is based on the assumption that no isolated treatment could be effective. It was considered essential that treatment be directed toward medical, psychologic and social aspects of the problem for the purpose of utilizing all procedures which should reasonably be expected to have beneficial results in rehabilitation. No attempt has been made to evaluate the separate aspects of the treatment. Since the cases were received from the court it was found possible to establish relatively adequate criteria of success and failure by observing the percentage of addicts taken off relief rolls and through figures showing the percentage of rearrests in the control and experimental group.

SUBJECTS

The subjects of this experiment were 513 chronic alcoholic addicts treated in the Municipal Court Clinic at Cleveland between Aug 1, 1940 and Oct 1, 1941 on charges of public intoxication. The group was composed of 901 per cent males and 99 per cent females, the average age of the total group being 39.2 years. Forty-eight per cent of the group were married, 31 per cent single and 21 per cent separated or divorced. The average years of alcoholism for these subjects was 11.1 years. They represented an average group of problem drinkers, most of whom had been repeatedly arrested on charges of intoxication.

Cases were obtained in the following manner. Through cooperation of the Municipal Court, arrangements were made with the presiding judges to impose relatively severe sentences of from three to six months' duration on all arrested alcoholic addicts. These addicts were then referred to us for treatment, largely on the basis of social and economic considerations. They were interviewed and examined as to their suitability for treatment. Efforts were made to encourage them to undertake treatment; it was emphasized that a permanent cure was possible and that treatment was free of cost to them. They were assured that every effort would be made to persuade the court to shorten their sentences (this having been prearranged with the court). It was explained to them that it would be much wiser for them to submit to the treatment than to be confronted with continued incarceration, severance of family ties and resulting economic loss. Only a few addicts (less than 5 per cent) refused to cooperate in the treatment program. Patients were released on probation after having served from ten to thirty days of their sentences; ambulatory treatment was then started immediately. These patients were to report to their assigned probation officer but were under no compulsion to report to the alcoholic clinic.

The control group of patients was secured from a large list of chronic alcoholic addicts who were brought before the court but not sent to the workhouse. The court deferred these cases from incarceration principally through consideration of vocation and family. All these patients had been arrested a number of times previously and the majority had been in the workhouse on at least one occasion in the past. I had no personal contact with any of the control group, but the court records were checked to determine the percentage of rearrests within a nine month period.

PROCEDURE

As mentioned before, the experimental subjects were contacted in the workhouse, at which time a thorough physical examination was made and the subject was informed on the treatment program. On their consent a series of interviews was held in which pertinent medical, psychiatric, occupational and social information was obtained from the patient. Remedial physical defects were corrected as far as possible and personal problems of the patient were discussed with particular reference to their association with the problem of alcoholism. After good rapport had been established, I interceded with the judge and obtained the patient's release—generally within ten to thirty days after incarceration. The patient was then told to report weekly to the clinic. In each case, cooperation of the probation officer and the patient's relatives was enlisted in an effort to keep in close contact with him.

Immediately on release amphetamine sulfate was administered in doses of 5 to 10 mg after breakfast

and after lunch, with exceptions being made when indicated. All medication was given orally, the object being to achieve satisfactory stimulation during the day and early evening hours while guarding against restlessness and insomnia at night. Amphetamine sulfate was not administered within the last eight hours before the patient retired. During the initial period of treatment, phenobarbital was frequently administered in $\frac{1}{2}$ grain (0.03 Gm.) doses, although occasionally larger doses were used. In some instances tepid baths of thirty minutes' duration were taken by the patients before retiring. While they were on amphetamine sulfate therapy, the patients were told to refrain from stimulating drinks, especially coffee or tea. Those who were particularly fond of coffee were allowed decaffeinated coffee. The patients were also strongly urged to consume large amounts of candy, especially during early abstinence, in order to maintain an adequate blood sugar level.⁸ Hard candy was recommended since in addition to being a good source of sugar, it also aided in salivation, which was generally reduced during the first week of treatment with amphetamine sulfate.

After four to six months of treatment cessation of daily medication was decided on on the following basis: total abstinence, satisfactory vocational and family adjustments, emotional factors, general attitude and improvement of the physical condition. At this time patients were given a supply of amphetamine sulfate and urged to use it as a substitute for whisky, if unable to control the desire to drink. After this the patients were instructed to report bimonthly to the clinic for observation.

Psychotherapy was employed in the form of reeducational measures and suggestions. The deleterious physical (especially neurologic) effects of alcoholism were stressed. The development of adverse habit patterns and the weakening of constructive social drives were emphasized. More intensive psychotherapy was attempted by investigating the various problems confronting the patients in their marital, vocational and social relationships. Attempts were made whenever possible to treat the underlying personality defects and mental conflicts. Patients were urged also to enter the Alcoholics Anonymous or one of the abstinent groups with which we cooperated in order to provide an abstinent social environment for the patient. In these groups, abstinent patients were encouraged to assist in the rehabilitation of others. Gabriel⁹ stated: "From the standpoint of successful psychotherapy the addicted individual must have another addiction to replace his former one, this should preferably be a social addiction." When necessary, social agencies and employment bureaus were utilized to assist in the solution of vocational problems.

Recreational and occupational programs were developed which included visiting, movies, exercise, games, reading, entertainment and the like. Social reeducation was developed when possible through the medium of active participation in abstinent group life and by encouraging the development of hobbies and interests. This intensive treatment was continued from one to six months, depending on the patient's cooperation and response to treatment; subsequent observations and follow-up were carried out, so that the total treatment of these patients ranged from four to fourteen months.

⁸ Strecker, E. A. and Chambers, F. T. *Alcohol One Man's Meat* New York: Macmillan Company, 1938, chap. 12.
⁹ Gabriel, E. *Psychiat. Neurol. Wchnschr.* 41: 500, 1932; 42: 505, 1932.

RESULTS

Over periods ranging from four to fourteen months, 513 patients were treated and observed. At the conclusion of this period 487 of the 513 patients were accounted for, contact had been lost with the remaining 26. Results are based on the 487 patients accounted for.

It was found that 397 patients, or 81.4 per cent, were abstinent and 90 patients had relapsed, 269 of these were followed up for a period of nine months or longer and the remaining 218 patients were followed up for periods of less than nine months. It was found that the greatest percentage of relapses occurred during the first month of treatment with a sharp drop in number of relapses through the third month and with no significant decline thereafter.

In July 1941, 167 patients of the 487 had been followed for nine months or longer. This group is compared in table 1 with a control group followed for the same period of time. It may be noted from this table that 25 per cent of the treated group were rearrested as compared with 42 per cent of the untreated group. Actually, the total number of rearrests for the control group was 191 as compared with 46 in the experimental group (table 2).

TABLE 1—Comparison of Number of Individuals Rearrested

	Number Rearrested	Percentage Rearrested
Treated Group 167 patients	42	25
Control Group 167 patients	70	42

TABLE 2—Comparison of Number of Rearrests

	Number of Rearrests	Percentage of Rearrests
Treated Group 167 patients	46	28
Control Group 167 patients	191	114

In order to determine the number who were on active relief prior to treatment, 200 patients who had been released from treatment were also investigated. Those receiving relief totaled 79, or 39.5 per cent of this group. Three months after the beginning of treatment, 36, or 18 per cent, remained on active relief. It was impossible to obtain a control group for this phase of the study.¹⁰

COMMENT

There has been for years considerable difference of opinion as to what constitutes a cure. Surely a patient should be termed abstinent rather than cured, and in some instances of moderate relapse the term "improved" is appropriate. In this study all patients who drank during the treatment period were considered as having relapsed, although a fair number of those who relapsed could have been regarded as relatively improved. No definite attempt was made to reevaluate these. In problem cases of the type treated such criteria as the number of individuals taken off relief rolls help to indicate the

decided differences in results obtained in treated groups as compared with similar untreated control groups.

Since the employment situation shows constant variation, it is difficult to compare employment of a group at different periods of time. During the time that this study was made there was a general upward trend in the employment situation, thus making it difficult to evaluate the results.

The fact that 58 per cent of an untreated group of chronic alcoholic addicts were not rearrested within a nine month period following release from incarceration may be taken as evidence that incarceration by itself may have some benefit, even though the figures show that rearrests are entirely too high to be considered satisfactory. The fact that there were 191 rearrests in the untreated group as compared with 46 for the treated group suggests that the present program was significantly effective in reducing the social cost of chronic alcoholism. No statement can be made concerning the permanent nature of these results, but there is no reason to anticipate any significant reversal in the direction of effect.

As far as I can determine, the control group was essentially similar in socioeconomic status to that of the treated group. The reduction in number of cases on relief following treatment is somewhat difficult to interpret with any high degree of accuracy since it was not possible to secure an adequate estimate on the percentage decrease of relief in the untreated group because of improved economic conditions. It is possible, though not probable, that untreated cases would also show a significant decrease on the relief rolls.

A conclusive statement cannot be made concerning the relative value of the various therapeutic factors used. I was favorably impressed, however with the use of amphetamine sulfate as an adjuvant in treatment, since it seemed to dissipate the apathy and depression following withdrawal of alcohol and in many instances facilitated the establishment of rapport with rather indifferent or negativistic patients. The drug appeared to produce an increased state of alertness, euphoria diminished emotional lability, greater ability to concentrate, greater activity drive and in many cases a feeling of wakefulness without apparent consciousness of fatigue. Overindulgence in this drug, however, may have detrimental effects in that it may produce irritability, restlessness, insomnia, anorexia, loss of weight, oral dryness and excessive diaphoresis.¹¹ In most instances fewer complications and better results were obtained with 5 mg. of amphetamine sulfate given after breakfast and after lunch.

From the early stages of the experiment, however, it was apparent that no one type of treatment would prove adequate, since the alcoholic patient required not only physical, psychologic and social readjustment but rather all three spheres were simultaneously impaired and in need of treatment.

CONCLUSIONS

A study of 513 patients who were treated and observed over a period ranging from four to fourteen months has revealed that

1 Of 487 patients contacted 397, or 81.4 per cent, were abstinent.

2 Comparison of 167 ambulatory patients who had been observed for a nine month period with an equal

¹¹ It was noted that while patients were on amphetamine sulfate medication the recovery rate from respiratory infections appeared retarded in almost every case. Frequently there was no alternative but to interrupt medication.

¹⁰ Martin H. Miller (Quart J Stud on Alcohol 3:34-44 [June] 1942) of the Department of Sociology of Western Reserve University making a study of arrests for intoxication in the Municipal Court of Cleveland found that in a group of 100 individuals charged with intoxication 85 per cent registered with at least one social agency of that community public or private. 75 per cent had at least one registration providing economic assistance in the form of food, rent, money or clothes. 24 per cent were known to at least six different agencies. 28 per cent were known to The Lodge, an institution for homeless and transient men, all but 10 of these had been arrested previously one or more times for intoxication. Of this total group 29 per cent were incarcerated in the Cleveland Workhouse. The entire group averaged 3.6 registrations with separate agencies per individual. The author on the basis of these and additional data concludes that intoxication cannot be treated as an isolated problem.

control group of untreated subjects revealed that 25 per cent of the treated group as compared with 42 per cent of the control group were interested.

3 There were 191 arrests in the untreated group as compared with 16 for the treated group.

4 The percentage of patients receiving relief dropped from 39.5 before treatment to 18 after treatment.

5 The present program of treatment for chronic alcoholism was effective in significantly reducing the social cost of this disorder.

6 In my opinion amphetamine sulfate proved to be of considerable value as an adjunct in the treatment of this disorder.

7 This study has demonstrated the great value of closer cooperation between the psychotherapist and the courts. In many instances the proper exercise of the right of sentence vested in our courts can be of great value as a therapeutic measure rather than a socially detrimental instrument as has frequently been the case in the past.

A AND B SUBSTANCES AS A CAUSE OF REACTIONS FOLLOWING HUMAN PLASMA TRANSFUSIONS

MILTON LEVINE, MS PHD

AND

DAVID STATE, MD

MINNEAPOLIS

The use of plasma and serum in the treatment of shock has become widespread since it offers advantages over whole blood in that both plasma and serum are more easily stored, transported and administered. Many workers¹ have stated that plasma, in reasonable quantities (arbitrarily set at 500 cc or less) may be administered safely regardless of the blood group. They have reasoned that the isoantibodies in the transfused fluid would be diluted by the recipient's blood beyond the point at which it would agglutinate the recipient's cells. On the other hand others² have emphasized the role of these same antibodies in causing transfusion reactions and have urged that either compatible plasmas be used or pooling be employed to decrease the titer of the antibodies. Despite the theoretical possibility that isoantibodies may cause reactions, there is no sound experimental evidence indicating that this is true for plasma. What evidence is available has been garnered from experience with universal donor blood. However, even this is not decisive. Gesse³ has published the most exhaustive study of reactions allegedly due to transfusion of universal donor blood, but his work has not been verified by other observers. Klendshoj and McNeil⁴ recently reported a reaction due to the administration of group O blood which illustrates the difficulties inherent in such a problem. In their case 250 cc of group O blood caused a reaction in a

group A recipient. They found the anti A titer of the administered blood to be 1:128 and the anti B titer to be 1:64. We have encountered such titers frequently in group O blood and have administered it when the titer was as high as 1:448 without observing any reaction. It would be difficult to rule out of the case reported⁴ the numerous nonspecific factors which are responsible for reactions in compatible transfusions. Our experience⁵ has indicated that reactions are no more frequent with universal donor blood than with blood of other groups, although we do admit the theoretical possibility of such reactions taking place.

Because concrete evidence for plasma reactions has not been presented there is a tendency among some clinicians to regard plasma as innocuous. However, reactions are encountered and have been reported in the literature.⁶ Our experience has been that plasma reactions are much less frequent than those following the administration of whole blood but that they do occur. In addition to the isoantibodies just mentioned, we have considered the transfer of allergens and pyrogens in administered fluid as a potential cause of reactions. These considerations have been theoretical, as an experimental approach we suggested earlier⁷ the use of cutaneous tests as a means of arriving at an understanding of the cause of these reactions.

We have reported in a preliminary communication⁸ that cutaneous reactions to one or more plasmas of the different blood groups, as evidenced by the formation of a wheal, occur in about 20 per cent of individuals tested. These cutaneous tests correlate with the occurrence of reactions following the administration of group specific plasmas. We found that many of the cutaneous tests and the transfusion reactions resulting from the administration of the plasma causing the cutaneous reaction could be attributed to the presence in the plasma of A and B factors. The occurrence in the plasma of the same antigen present in the erythrocytes in group A and B bloods was first reported by Schiff,⁹ who found A substance in the serum of group A bloods. We have confirmed recent reports that these substances occur in A and B plasma. The presence of these factors would account for the disappearance of the isoantibody titer in pooled plasma and serum, a fact which was observed by Levinson and his co-workers¹⁰. They however offered no explanation for the phenomenon.

We are presenting a series of 6 cases reacting to the transfusion of either group specific plasma or purified A and B substances.¹¹ The latter has been presented by Witelsky and his co-workers¹² as a means of reducing the titer of the isoantibodies in universal donor blood. The substances are added to the group O blood and the whole is administered without further preparation. These workers have claimed that the A and B substances are entirely innocuous when administered intra-

venously, although Witebsky¹³ has stated that he has encountered a number of severe reactions resulting from the administration of group O blood treated with the A and B substances. He attributes the reactions however, to causes other than these substances.

Plasma used in this study was siphoned off blood which was permitted to sediment for twenty-four to seventy-two hours after being drawn. Sedimentation took place at temperatures of from 4 to 8 C. Cutaneous tests were performed by injecting 0.05 cc of the plasma intradermally on the volar surface of the forearm. A positive cutaneous test was indicated by the formation of a wheal of from 0.8 to 3 cm in diameter. This wheal appeared in ten minutes after the injection, reached a maximum after thirty minutes and began to fade at the end of one hour. The A and B substances were obtained combined in 10 cc lots for administration in 500 cc of whole blood. We used, instead, 500 cc of isotonic solution of sodium chloride for intravenous administration. For the cutaneous test with the A and B substances, 0.05 cc of a 1:50 dilution of the original material was employed. Wheal formation was the same as for plasma in positive cases.

REPORT OF CASES

CASE 1—G. H. a man aged 41, of blood group O, with multiple sclerosis, developed chills, severe dyspnea and cyanosis on Feb. 25, 1942, following the intravenous administration of 150 cc of undiluted group A plasma. He was relieved by the intramuscular injection of 1 cc of 1:1,000 solution of epinephrine hydrochloride. Cutaneous tests were made on March 12 and 13. Three separate group A plasmas gave positive reactions; three group B and an O plasma gave negative results. It was possible to transfer passively the cutaneous sensitivity to 4 other individuals. He was given an additional 100 cc of group A plasma on March 20 with resultant chills, cyanosis and dyspnea. These symptoms were relieved by the intramuscular injection of 0.5 cc of 1:1,000 epinephrine hydrochloride. The patient was subsequently given several group O and group B plasmas intravenously without incident. On May 25 the patient was given cutaneous tests again with O, A, B and AB plasmas. Groups A and AB plasma alone gave positive reactions. Cutaneous tests were also positive to the injection of equal parts of group A and B plasmas.

CASE 2—L. H. a man aged 30, of blood group O, had suffered traumatic amputation of the right leg. On April 3, 1942, cutaneous tests were positive to group A plasma and negative to groups B, O and AB plasma. The intravenous administration of 100 cc of undiluted type A plasma was followed almost immediately by nausea, dyspnea, generalized itching and urticaria. The symptoms were relieved by the intramuscular injection of 0.5 cc of 1:1,000 epinephrine hydrochloride. On April 6 three separate group A plasmas gave positive cutaneous reactions. Cutaneous tests to groups B, O and AB plasma were negative. The intravenous administrations of 100 cc of group O and B plasmas were not followed by reactions. On April 11 the patient was given 150 cc of undiluted AB plasma with resultant generalized erythema and urticaria lasting one and one-half hours. Cutaneous tests with this plasma were not done prior to administration. On April 11 cutaneous tests to a group AB plasma were positive and the intravenous administration of 75 cc of this plasma resulted in the appearance of two regions of erythema and urticaria 3 inches in diameter, on the back of the patient's neck. On June 6 cutaneous tests to combined A and B substance and group A plasma were positive. The intravenous administration of 500 cc of combined A and B substance diluted to 1:50 with isotonic solution of sodium chloride was followed, after 10 cc had been given, by generalized erythema, dyspnea and cyanosis. These symptoms were relieved quickly by the intramuscular injection of 0.5 cc of 1:1,000 epinephrine hydrochloride.

CASE 3—E. K. a man aged 45, of blood group B, with lupus erythematosus, gave positive cutaneous tests for group A and AB plasmas and negative tests for O and B plasma. On March 10, 100 cc of B plasma was given intravenously without reactions. On March 15 the intravenous administration of 120 cc of undiluted group A plasma was followed by cough, dyspnea and a sense of constriction of the chest.

CASE 4—S. L. a woman aged 47, of blood group O, with Banti's disease, had erythema, dyspnea, chills and a fever of 106 C on May 17, 1942, immediately after the intravenous administration of 100 cc of undiluted B plasma. On May 18 cutaneous tests to four separate B plasmas and two AB plasmas were positive. Group O and A plasma cutaneous tests gave consistently negative results. Subsequently she was given multiple transfusions of group O and A plasmas without reactions. On May 19 cutaneous tests to combined A and B substances were positive. Unfortunately the patient died before it was possible to give the diluted combined A and B solutions.

CASE 5—C. S. a youth aged 18, of blood group B, had a fracture of the mandible. On June 2, 1942, cutaneous tests for A and B substances were strongly and those to A and B plasma weakly positive. The intravenous administration of 10 cc of 1:50 solution of combined A and B substances was followed by generalized erythema, dyspnea, rapid pulse and bleeding from the mucous membrane of the mouth and nose. These symptoms were relieved by the intramuscular injection of 0.5 cc of 1:1,000 epinephrine hydrochloride.

CASE 6—R. T. a man aged 47, of blood group O, with chronic osteomyelitis of the left femur gave positive cutaneous tests to A plasma and combined A and B substances on June 15, 1942, and negative tests to O, B and AB plasmas. These tests were repeated on June 16 with the same results. On June 17 cutaneous tests were positive to group A serum and negative to group O serum. On June 16 ten minutes after the intravenous administration of 200 cc of A serum the patient complained of slight epigastric distress, 'light headedness' and dyspnea. These symptoms were relieved by the intramuscular injection of 0.5 cc of 1:1,000 epinephrine hydrochloride. On June 18 the patient was given 500 cc of diluted combined A and B substances intravenously. After 100 cc had run in the patient had severe pain in the back, sneezing, cough, generalized erythema and dyspnea. The pulse rose from 80 prior to the administration to 104 per minute. There was no elevation of temperature. The symptoms were relieved by the intramuscular injection of 0.5 cc of 1:1,000 epinephrine hydrochloride. The sites at which groups A and AB plasmas and A and B substances had been injected subcutaneously on the previous day again became elevated and developed surrounding erythema.

COMMENT

From the foregoing it is obvious that the A and B substances present in the plasma, and the purified combined A and B substances may cause reactions after intravenous administration in sensitive persons. This sensitivity is not associated with any particular blood group in the recipient or in the donor. It occurs when the recipient has the antibody corresponding to the administered antigen, but not every person having the antibody will react to the transfused antigen. We have had patients of all blood groups who have shown no plasma sensitivity by either cutaneous test or intravenous administration. The reason for the existence of sensitivity in certain individuals remains to be explained. It may merely be a quantitative phenomenon. We find some evidence for differences in the degree of reaction in the cases studied. These differences may be attributed to variations either in sensitivity of the recipient or in the amount of antigen administered in the transfused material. We have some evidence for the latter. Group AB plasma gives

smaller wheals in sensitive persons than do A or B plasmas alone. We would expect this, since it is known that there is usually less antigen present in group AB cells than in A or B cells. In fact in some cases in which cutaneous sensitivity to A and B substance was uniformly present the response to injected AB plasma was variable. This is further evidence that quantitative variations in the sensitivity response depend on the amount of antigen present. Additional confirmation of this point is obtained from the results of the cutaneous tests with purified A and B substances. The positive responses vary in intensity with the dilution of the original material used in the tests. The more concentrated solutions give more pronounced cutaneous responses as measured both by the size of the wheal and by the degree of induration.

Because the preparation of A and B substances is such as to require their combination in the final product we had to use this combination for our tests. We obtained positive cutaneous tests only in those cases that showed a positive response to injection either of group A or of group B plasma. In cases 5 and 6 we were able to confirm our results by the use of a purified A substance which we obtained from Dr. Witelsky late in the experiment. The purified A substance gave a positive cutaneous test in persons who had previously responded to the injection of A plasma and the combined A and B substance. Diluted A and B substances were given intravenously to patients with negative cutaneous tests without reactions.

In the last 500 routine transfusions of plasma at the University Hospitals, the reactions occurring have all been traced to the A or B substance in the plasma. Since many hospitals are now preparing their own plasma, it becomes a matter of great importance to avoid these reactions. The absence of reactions when the cutaneous tests are negative suggests the use of such tests as an adjunct to plasma therapy. This is especially true of unpooled plasma. We do not as yet know what pooling will do, but preliminary results indicate that combination of antibody and antigen, such as occurs in pooling, does not remove the cutaneous reacting properties of the antigen (case 2). Although plasma has been used in most instances in this study there is no reason to believe that serum would yield different results, since A and B substances are found in both serum and plasma.

CONCLUSIONS

1 Reactions followed the intravenous administration of plasma. These reactions are due to the A and B substances present in the plasma. This is confirmed by the response of sensitive individuals to the intravenous administration of purified combined A and B substances. Cutaneous tests in sensitive persons are positive to the plasma causing reactions and to the purified combined A and B substances. This sensitivity is not specific to any particular blood group.

2 We have not observed reactions following the intravenous administration of plasma which gave a negative cutaneous test. Cutaneous testing should form a valuable adjunct to plasma therapy.

3 Since purified A and B substances give rise to reactions, more work on these substances is necessary before their use in universal donor blood becomes routine.

GENU RECURVATUM FOLLOWING POLIOMYELITIS

A CONTROLLED METHOD OF OPERATIVE CORRECTION

C. E. IRWIN, MD
WARM SPRINGS, GA

The presence or absence of structural changes in the tibial condyles serves to differentiate the two types of genu recurvatum. The presence of structural changes in one type¹ and the complete absence of these changes in the other can be explained by the variation in the underlying causative factors. The mechanism by which each type develops is determined by these different underlying causes.

HYPERTENSION CHARACTERIZED BY SKELE- TAL CHANGES

The chief underlying causative factor in the first group is the lack of sufficient power in the quadriceps group to lock the knee in extension against resistance. In a typical case the hamstrings have a normal rating are not stretched out and may even be short. The calf group is normal usually contracted and stronger than normal. A short achilles tendon develops and the calf becomes overdeveloped because of necessity, the meta-

Fig. 1—Genu recurvatum characterized by skeletal changes in the tibia. Note elongation of the condyles posteriorly and posterior bowing of the upper tibial shaft.

tarsal heads are brought in contact with the floor when weight is borne on this side. This point of first contact is in a plane anterior to that in which the knee joint lies. The distance from the metatarsal heads to the insertion of the achilles tendon represents the arm of a lever through which the calf group exerts its force. The resultant force of this muscular effort is directed backward against the posterior structures of the knee joint. There is an exaggerated spring in the step. The normal posterior thigh and calf muscle groups are resistant to stretching.

The changes that account for hyperextension are found in the condyles and upper third of the tibial shaft. The condyles are elongated posteriorly. Normally the tibial plateau forms an angle of approximately 90 degrees to the shaft. Because of these condylar changes this angle becomes more acute. A posterior bowing in the upper third of the shaft is usually present, and in many cases there may be partial subluxation of the tibia. This deformity develops rather slowly over a long period of time. According to Wolff's law, "the change in static relations of bone leads to changes in structure and physiologic function."

Read before the Section on Orthopedic Surgery at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

¹ These structural changes were first called to my attention by Dr. Michael Hoke.

HYPEREXTENSION WITH ABSENCE OF SKELETAL
CHANGES—SOFT TISSUE STRETCH

Weakness in the calf and hamstring muscles is the underlying cause of the deformities comprising the second group (fig 2). In the presence of this weakness the hyperextension develops rather rapidly. There are no structural changes in the tibia. Elongation

Fig. 2—Genu recurvatum characterized by absence of skeletal changes in tibia. The posterior soft tissues have been elongated by stretching.

of the calf and hamstring muscles followed by stretching of the posterior capsular ligaments will allow the joint to hyperextend. A calcaneus or calcaneovalgus deformity of the foot is usually present on the same side. These deformities can and often do develop before weight bearing is attempted. Under weight bearing conditions patients with this condition are able to keep the knee insecurely locked in extension by an abnormal shift in body weight and not by the substitution of normal muscle power on the flexor aspect of the knee. The gait is made conspicuous by the absence of any spring in the step. By flexing the trunk on the thigh with a backward twist of the body, the patient rocks back on the heel and in this manner is able to maintain the body weight in a plane posterior to that of the knee. This abnormal shifting of body weight keeps the joint in extension when the weight is borne on this side, but the repeated thrusts of this weight backward against the posterior structures of the knee cause the joint to hyperextend by stretching the soft tissues.

Surgical procedures designed to correct genu recurvatum must fulfil two requirements of equal importance:

Fig. 3—Proposed osteotomy sites.

First, the mechanical alignment of the hyperextended extremity must be properly restored, and, second, following restoration of the mechanical alignment the underlying causative factors of the deformity must be so altered that the hyperextension will not recur from the original mechanism.

The prognosis following surgical correction is entirely different in the two types. This is the practical reason

for making the differentiation. The prognosis is excellent in the first type, which is characterized by skeletal changes in the tibia and normal muscle power behind the knee. After the hyperextension has been corrected the underlying cause can be altered simply by transplantation of one or more of the hamstrings to the patella. When the person resumes weight bearing he will be able to lock his knee from action of the transplanted muscle, and it will not be necessary to substitute action of a strong calf group, as has been described. The prognosis is extremely poor in the second type, in which there are skeletal changes in the tibia and no power of functional value in the calf group or hamstring muscles. Regardless of the method used to restore the alignment, the deformity will recur when weight bearing is resumed because there is no way to change the original cause. There are no available muscles to transplant forward which would enable the person to keep the knee hyperextended without shifting his weight as he did prior to the operation. Usually a long brace is eventually necessary to keep these extremities in good alignment.

Fig. 4—Osteotomies completed. Proximal fragment maintained in hyperextended position by Kirschner wire incorporated in plaster.

The operation to be discussed in this paper is concerned with the correction of the hyperextension and not with the secondary procedure that is necessary to alter the underlying causative factors. Several procedures have been designed to correct hyperextension of the knee. The best known are those described by Campbell,² in which he constructs an anterior block by fusing the patella to the tibia, and by Mayer,³ who forms an anterior block by using a free graft from the tibia. Both of these procedures are extensive operations and entail exposing the knee joint. Gill⁴ shortens and reinforces the posterior structures of the knee with a strong check ligament made by lacing strips of fascia lata to the periosteum and lateral ligaments. Carrell⁵ strengthens the soft structures by constructing a check ligament made by lacing fascia lata directly into the posterior surface of the femur. Both of these procedures are quite extensive and present technical difficulties. I have had no experience with these operations. All seemed a little more extensive than was necessary to correct the ordinary deformity. The method to be described in this paper is so simple both in mechanical principle and in execution that I hesitate to present it as an effective operative

2 Campbell, Willis C. *Operative Orthopedics*. St. Louis: C. V. Mosby Company, 1939.

3 Mayer, Leo. An Operation for the Cure of Paralytic Genu Recurvatum. *J. Bone & Joint Surg.* 12: 845 (Oct.) 1930.

4 Gill, A. B. Operation for Correction of Paralytic Genu Recurvatum. *J. Bone & Joint Surg.* 13: 49 (Jan.) 1931.

5 Carrell, W. B. Use of Fascia Lata in Knee Joint Instability. *J. Bone & Joint Surg.* 19: 1018 (Oct.) 1937.

procedure. On the other hand, the value of any operation is enhanced by the comparative simplicity with which the desired end results can be obtained. The method to be discussed consists simply of an osteotomy of both tibia and fibula. The osteotomy of the tibia is done at the level of the tibial tubercle well below the epiphysal line (fig 3). This operation and the method of controlled correction are carried out in the following manner:

TECHNIC OF OPERATION

A section of shaft approximately 1 inch in length is removed at a point just below the neck of the fibula. This defect is packed with bone shavings made from the sectioned piece of bone. The periosteum and overlying tissues are closed in the usual manner. Through a second incision the upper fourth of the tibia is exposed and osteotomized as shown in figure 4. The joint is not disturbed. The tongue attached to the lower fragment is cut out of the anterior cortex with a thin osteotome. The use of a thin osteotome to

Fig 5—Application of single spica. Weight of the extremity maintains the proximal fragment of the tibia in hyperextension.

cut out the tongue prevents the loss of bone substance around the edges and the tongue fits snugly when it is later replaced in the recess in the upper fragment. A Kirschner wire is now passed through the distal end of the proposed upper fragment before the tibial shaft is completely divided. The wire should be inserted at right angles to the vertical axis of the knee joint and parallel to its lateral plane. The osteotomy is completed with either a Gigli saw or an osteotome. The proximal part of the distal fragment is lifted out of its periosteal bed and a wedge of bone of predetermined size is removed from the shaft, the base of wedge corresponding to the posterior cortex. The tongue is replaced in its recess in the upper fragment and the two ends of fragments are pushed firmly together (fig 4). The periosteum, which is quite thick in this area, is firmly fastened over the tongue. This is all the fixation necessary to keep the fragments in position until a cast can be applied.

The patient is now placed on a fracture table and the extremity is suspended to an overhead arm by means of a chain fastened through the Kirschner bow. The weight of the extremity plus additional pressure applied to the anterior aspect of the distal thigh hyperextends the proximal fragment to its fullest extent (fig 5). With the extremity in this position a single spica is applied down to and including the wire in the

hyperextended fragment. This portion of the cast is allowed to harden. The pelvis, femur and hyperextended fragment of the tibia are thus immobilized as a unit. The distal fragment remains free for manipulation in any direction desired. It can be flexed to correct the hypertension, rotated inward or outward to correct any preexisting torsion or moved from side to

Fig 6—Postoperative appearance. Note alignment of tibial shaft to the plateau.

side to overcome any varus or valgus of the tibia. When the desired position is obtained the cast is completed. Postoperative roentgenograms are made to check the result. If any changes in position of the fragments are necessary they are easy to make by simple plaster wedgings distal to the incorporated wire. These changes can be made at the end of ten days or two weeks without an anesthetic and with no discomfort to the patient. The Kirschner wire is removed at the end of six weeks and the spica replaced by a leg cast extending from the toes to the groin. Eight weeks is usually sufficient for complete union (figs 6 and 7). A full range of joint motion is secured before the secondary procedure to alter the underlying causative factors is carried out.

SUMMARY

There are two separate and distinct types of genu recurvatum which follow an attack of polyomyelitis. These deformities have been discussed from the standpoint of causative factors, the mechanism of development, the pathologic changes and the prognosis following surgical correction.

A simple operative procedure has been adopted as an effective means of correcting the deformity. The

Fig 7—Typical end result.

method is not extensive, does not necessitate exposure of the knee joint and presents no technical difficulties.

The actual correction is easily controlled, and the position of the fragments can be easily changed in any desired direction by simple cast wedgings.

It has been my experience that those deformities, in which the underlying cause cannot be altered, will recur unless they are properly supported by a long brace.

ABSTRACT OF DISCUSSION

DR HAROLD B BOYD, Memphis, Tenn Poor end results often follow the treatment of paralytic genu recurvatum Dr Irwin's division of these cases into two types, those with and those without structural changes in the tibia, should help in selecting the proper operative procedures The patients with flail extremities or with severe paralysis are difficult to treat and, as he states, usually require braces Occasionally there are exceptions to this rule Patients who are financially unable to obtain braces or keep them in repair may be better off with an arthrodesis of the knee This is especially true of laborers In studying our patients we found that the best end results followed osteotomy, the second best followed the anterior bone block devised by Dr Campbell In my experience soft tissue operations for genu recurvatum have not been successful, as the reconstructed ligaments tend to stretch with use and time I have not used the osteotomy which Dr Irwin has described The mechanics of the procedure, however, appear excellent and I hope to be able to try it in the future

DR A BRUCE GILL Philadelphia A moderate genu recurvatum or hyperextension of the knee is often vulnerable to a patient who has paralysis of the quadriceps femoris muscle Weight can be borne on the foot if the knee will go into moderate hyperextension This eliminates the necessity for action of the quadriceps in bearing weight One of the operations which I have done most commonly in cases of paralysis of the lower extremity was a supracondylar osteotomy of the femur to correct knock knee and make a back knee The operation which I designed and have employed is for the correction of extreme backache The patients are able to bear weight on the foot with this condition, but the extreme backward bowing at the knee is disabling and at times is painful As extreme genu recurvatum is due essentially to relaxation and stretching of the soft structures posterior to the knee joint, my operation was designed to strengthen those structures or to substitute for them a strong band which would serve as a check ligament to prevent overextension of the knee I believe that this might well be called a physiologic procedure, as it is restoring strength to structures which are designed to prevent hyperextension This procedure was not designed for the first type of case which Dr Irwin has discussed but is designed essentially for the flail extremity which results from infantile paralysis I have observed that the results of my operation, if properly done, are very gratifying Patients have been under my observation for a good many years after the operation and there has been no relapse in after years If the operation is not done strictly in the manner described in my publication the results will be poor The check ligament which is constructed behind the knee must necessarily be inserted into the leg below the knee In other words, it must span the posterior aspects of the joint If the lower attachment of it is near the knee joint the result will be poor

DR H R MCCARROLL, St Louis Five years ago I had the opportunity of seeing Dr Irwin do one of these osteotomies and I was impressed with the simplicity of the procedure when compared with other procedures used for correction of the recurvatum deformity I have had occasion to use it in a few cases and I am convinced that it is based on sound mechanical principles The type of extremity in which I have employed this procedure is primarily the extremity with sufficient muscle power to permit weight bearing without a brace but in which a thigh brace has been continued because of the presence of some recurvatum deformity It should not be used in the flail extremity when there is no hope of discarding the brace I have combined the osteotomy at times with lengthening of the heel cord in cases in which the short heel cord served as the deforming factor because of the pull exerted through the two heads of the gastrocnemius muscle The best result is in a 14 year old girl whose biceps and semitendinosus had been transplanted to the patella previously for replacement of a paralyzed quadriceps, as I felt at the time that the semimembranosus and the two heads of the gastrocnemius were normal These, however, were not as strong as the transplants and some genu recurvatum developed with discomfort in the back of the knee An osteotomy corrected the deformity, relieved

the necessity of reapplying a brace and relieved her discomfort The result is still satisfactory after two years The discomfort felt by these patients is relieved because a straight line of weight bearing is reestablished and this eliminates the strain which was exerted on the posterior capsule and posterior ligaments of the knee joint The osteotomy which I employ has differed from Dr Irwin's in that I divide the bone anteriorly and open the wedge rather than posteriorly and close the wedge There is some shortening in many of these extremities, and this prevents further increase in the shortening

DR C F IRWIN, Warm Springs, Ga I enjoyed Dr Gill's remarks concerning the particular operations which he has done and am sure that in his hands the results have proved successful I do not think Dr Gill meant to say he would do an osteotomy of the femur if the location or the deformity was in the upper third of the thigh, as has been shown in the first case Of course, the osteotomy would be done at the site of the architectural changes It is impossible to place accurately in two separate and distinct groups all the deformities of genu recurvatum following poliomyelitis The two groups presented today represent the extremes and are entirely different as to their pathologic condition the cause and the method of formation The only advantage I see of doing the osteotomy as described today is that it gives one perfect control over the fragments It you do not get all the correction you desire at the time of operation the position can be easily changed in ten days to two weeks without an anesthetic and without any discomfort to the patient by doing simple plaster wedgings

Clinical Notes, Suggestions and New Instruments

PNEUMONIA APPARENTLY DUE TO TRICHOMONAS BUCCALIS

NATHAN GLAUBACH MD AND F J GULLER MD
DALLAS TEXAS

History—G L C, a white man, admitted to the hospital on May 6, 1942, complained of pain in the back The onset of this illness occurred two weeks prior to admission with generalized aches and pains over the entire body and a feeling of malaise and weakness Eight days prior to admission a pain developed in his back Four days prior to admission he concurrently had a severe cough and pain on the left side of the chest The cough was productive of a white, frothy phlegm At no time was blood noticed in the sputum The patient was nauseated and vomited a great deal The pain in the left side of the chest became more severe and was aggravated by coughing

The patient gave a history of the usual childhood diseases—influenza and pneumonia while in the Army and a history of nervous attacks during which he jerked around and fell to the ground but otherwise his past medical history was essentially negative

His mother died of tuberculosis at the age of 56, his father died at the age of 86 of heart disease Four brothers and two sisters are living and there is no history of diabetes, cancer or insanity in the family

Physical Examination—The patient was poorly nourished was approximately 5 feet 7 inches (170 cm) in height, weighed about 105 pounds (47.6 Kg) and appeared acutely ill His temperature on admission was 102 F, pulse rate 120 and respiratory rate 28

Head, scalp and eye, ear, nose and throat findings were essentially negative and irrelevant with the exception that he had a far advanced pyorrhea and many teeth were missing

There was restriction in respiratory mobility in the lower left part of the chest tactile fremitus was increased, and there was dullness to percussion in the same area The breath sounds were bronchial and numerous moist rales were heard just above the area of dullness

Cardiac, rhinological, genitourinary, orthopedic and neuro-psychiatric examinations were essentially negative.

COMMENT

At the time of admission the physical examination indicated that the patient was suffering from an acute respiratory infection presumably left lower lobe pneumonia. Sputum typing for pneumococcus was immediately ordered and the patient was given an initial dose of 60 grains (4 Gm) of sulfadiazine at once. The laboratory report was returned within a short time showing the pneumococcus typing, (Neufeld method) negative for all types. Microscopic examination of the untreated sputum showed a tremendous number of actively motile organisms morphologically similar to *Trichomonas buccalis*. A repeat examination of sputum was then ordered and similar results were obtained.

A scraping was made from the mouth and the various foci of infection about the gums and teeth to determine if the sputum was contaminated by *Trichomonas* organisms from this source. Examinations of this material were negative for *Trichomonas* and treatment was continued with sulfadiazine 15 grains (1 Gm) every four hours. The patient's temperature, which on admission was 102 F and which became elevated to 103.8 F shortly after admission dropped slowly over a period of four days to 99 F where it remained for slightly more than a week before dropping to normal. Daily sputum examinations showed a decrease in the number and the motility of *Trichomonas* organisms and finally disappearance of these organisms from the sputum.

The sulfadiazine level of the blood was 36 mg per hundred cubic centimeters on May 11 five days after admission.

In an attempt to find other sources of *Trichomonas* infections routine stool examinations were instituted and on examination many motile amebae containing red blood cells were found which were reported as *Endameba histolytica*. Repeat examinations were ordered on stools and again these organisms were found, but *Trichomonas* was not to be seen. The patient was thereupon questioned with regard to the possibility of his having had previous symptoms of dysentery. This he stated that he had not had. He has never been in the tropics and stated that he never had any acute symptoms of dysentery. He was treated with carbarsone receiving three $\frac{3}{4}$ gram (0.045 Gm) capsules three times a day for two days and then three $\frac{3}{4}$ gram capsules twice a day for seven additional days. Repeated stool examinations at the end of the period of treatment were negative for organism morphologically similar to *Endameba histolytica*.

X-ray examination on admission showed a hazy density with slight accentuation of pulmonary markings of the lower left lobe. There was also a defect in the fifth rib on the left side anteriorly attributed to a fracture. X-ray examination on May 11 showed slight decrease in the density of the lower left lobe as compared with the previous film. The patient's critical symptoms were much improved on May 26 when another roentgenogram of the chest was made and at this time there were still residuals of the pneumonic process as evidenced by heavy mottling of the pulmonary markings. Clinically the patient had recovered.

SUMMARY

This case is unique in that all signs of an acute respiratory infection indicated that the process was a left lower lobe pneumonia. No pathologic organisms could be discovered in the sputum to cause this other than organisms morphologically identified as *Trichomonas buccalis*. These were found in great quantities. The source of this infection or how it came about could not be determined. A review of the literature fails to reveal a report of any case similar to this. Volume IV of Osler's *Modern Medicine*, published in 1927, mentions a case of gangrene of the lung due to *Trichomonas intestinalis*. The newer textbooks in medicine and diseases of the chest make no reference to this organism as a cause of respiratory infections.

Whether the pulmonic process is directly attributable to the *Trichomonas* organisms or whether the organisms were a secondary invader cannot definitely be stated. It is to be noted, however, that initial examinations of the sputum showed this organism present in tremendous numbers and very actively

motile and that the motility of the organisms decreased and finally disappeared from the sputum with sulfadiazine therapy.

The patient was discharged from the hospital on June 4, 1942 apparently cured after having been critically ill for at least one week. Examinations of sputum and stools showed no recurrence of the *trichomonas* or *histolytica* organism.

A NEW SURGICAL SUTURING INSTRUMENT WITH A CONTINUOUSLY THREADED NEEDLE

HENRY I. GOODMAN, M.D., NEW YORK

All factors considered the ultimate result of good surgical technique is measured by the extent of the restoration of function. Among the factors responsible for such a result is the accurate and adequate apposition of tissues to promote proper healing. The problem of suturing technique has, therefore, always been of paramount importance to the surgeon.

ENDWISE FOR FORWARD STITCHING

Fig. 1—Different settings of the needles

Fig. 2—Threading the instrument

The introduction of new surgical suturing instruments has generally been the result of the requirements of a new surgical technique. It is equally true, however, that the introduction of new instruments has introduced a better technique. During the past fifty years approximately one hundred and twenty-three new suturing devices have been described in the literature. This in itself is an indication of the interest which the surgical profession has shown in the technique of suturing. Very few of these instruments are in use today.

The present instrument collectively offers many advantages possessed individually by several instruments. In addition, several new features have been introduced which are unique. The sudden changes in the hospital personnel have at this time considerably interfered with the smooth efficiency of almost every surgical service. Continued use of this instrument has easily demonstrated how much it can contribute not only in

effecting an economy in suture material but in definitely aiding a depleted personnel to carry on with increased efficiency

The instrument is made of stainless steel with a duralumin handle finished in black. This finish is unaffected by steriliza-

once inserted, remains fixed during the entire suturing procedure at the position that the operator has found most convenient

The handle of the instrument is hexagonally grooved and has within it a tension spring

Fig 3—Section of instrument

Fig 4—Steps in making a suturing stitch which may be removed by cutting the knots at both ends and withdrawing the suture in a single strand

Fig 5—Technic for interrupted sutures

Fig 6—Technic for interrupted sutures

tion There are three component parts a needle clamping control nut at the base of the handle, a spool holder, easily controlled by thumb pressure, and a special type of needle clamp at the end of the instrument (fig 3) Needles are interchangeable and can be set at several different angles (fig 1) A needle,

With this instrument, a variety of stitches become possible, some of which are entirely new in the field of surgical technic and possess decided advantages A few of these new sutures and the technic of making them are illustrated (figs 5 and 6) By simply cutting away the first and last knot of certain of

which enables the position of the needle to be adjusted easily to a new position without the possibility of the needle falling out and becoming lost The fenestrated spool fits into a holder in such a way as to reduce contamination to a minimum Owing to a simple self-locking device, the suturing material on the spool can not unravel, and the amount that can be withdrawn is entirely controllable by slight thumb pressure on the control knob The spool has a capacity of about 53 feet of C silk. Catgut nylon cotton and alloy steel wire may be used instead of silk The entire instrument with the loaded spool may be sterilized by boiling or autoclaving

These spools are easily wound The spool winder is first attached to the handle of the instrument beneath the loosened clamping nut The suture material is first passed through a tension spring arrangement and then inserted into the spool through one of the side openings (fig 2) With the aid of this tension control, the spool can be uniformly and quickly wound with suture material simply by twirling the spool holder as illustrated (fig 7)

The needles devised for this instrument are of various sizes and shapes and readily interchangeable Some of the larger needles have a finely ground lance edge on one side By virtue of the particular design of these needles and the position of the lance edge, penetration through the firmer tissues is easily effected Of equal importance is the use of this lance edge in cutting the suture after the knot has been tied thus greatly facilitating suturing (fig 9) Catgut and fine wire do not lend themselves to being cut by this lance edge Each needle, regardless of how fine has two eyes through which the suture material is threaded This arrangement prevents unthreading of the needle The suture material always rests in a groove on the under surface of the needle to reduce trauma All needles are made of finely tempered steel and are chromium plated

the continuous sutures the entire suture may readily be removed in a single strand

The outstanding features of this instrument are

- 1 This instrument simplifies and improves suturing technic
- 2 It may be used equally well for superficial and deep suturing

8 The large capacity of the spool for suture material saves rethreading during an operation

9 The amount of suture material is easily controlled by thumb pressure on the spool release

10 A variety of interrupted and continuous stitches are possible with this instrument, some of which are new in surgical technic

11 It is readily taken apart for cleaning and easily reassembled

57 West Fifty-Seventh Street

THREE PRIMARY SYPHILITIC LESIONS IN ONE PERSON OVER A TEN YEAR PERIOD

JOHN R. HERMAN, M.D.
Lieutenant (j g) U S N R

"The reporting of a valid reinfection is one of the most difficult accomplishments in the syphilological field and the larger part of the evidence now in existence for individual cases must rank as presumptive or suggestive rather than conclusive." With this in mind, and with the full realization that the bibliography available on a destroyer is quite limited the following case is presented for record. No comparable cases have come to my attention or to the attention of various medical men with whom I have been able to consult

PIPOIT OF CASE

First Lesion—B. R. L. a white man born in 1912 was exposed to venereal infection in Shanghai in December 1932 and forty days later had a primary coronal lesion. Dark field examination was negative but a Kahn reaction was found to be 4 plus one month later. The patient also developed "general adenopathy." Antisyphilitic treatment was started in 1933 and the patient received 14 Gm of arsenicals and twenty-four injections of a bismuth compound prior to 1935. He remained untreated until 1937, when for no recorded reason, under the care of a different medical officer, he was again started on treatment and received 115 Gm of neoarsphenamine and 41 Gm of bismuth subsalicylate. His Kahn reaction remained negative after January 1934 except for one 2 plus Kahn reaction which was followed by four negative reactions the last of these in February 1938. No spinal tap was made and no history of secondary lesions noted.

Second Lesion—In August 1938 the patient had a venereal exposure in Hong Kong which was followed in two weeks by the development of a coronal sulcus lesion. Dark field examination revealed the presence of *Treponema pallidum* and shortly thereafter a Kahn reaction was 4 plus. "Generalized adenopathy" was noted this time again. Antisyphilitic treatment while started at once, was quite sporadic, owing to the patient's migratory profession. Between August 1938 to 1940 however, the patient received 178 Gm of mapharsen and 473 Gm of bismuth subsalicylate and 6 cc of iodobismutol. By his next Kahn test in July 1939 he was again seronegative. Again no spinal tap was done, and no secondary lesions were noted. No further follow-up is recorded after August 1940, but the patient states that a Wassermann test was done by a private laboratory in 1939 which was reported as 2 plus and that several Kahn tests were done thereafter, the last in 1941. All of these were negative.

Third Lesion—This resulted ten days after an unprotected exposure in Scotland in 1942. The primary lesion here became deeply ulcerated near the preputial reflexion, surrounded by an area of cartilaginous-like induration. Successive dark field examinations resulted in two definite positives, and five weeks after development of the lesion the patient again had a 4 plus Kahn reaction. Antisyphilitic treatment was started immediately. The penile lesion cleared up rapidly under arsenicals and local application of sulfanilamide powder. A spinal tap was done and was entirely negative. There are no secondary symptoms.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U S Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

1 Stokes J H. Modern Clinical Syphilology ed 2 Philadelphia W B Saunders Company 1934

Fig 7—Winding spool

Fig 8—Cross section showing that slight pressure on the thumb nut (O) moves the spool away from the screw (N) allowing the spool to turn freely

Fig 9—The suture is quickly severed after each stitch by the keen knife edge of the lance point needle

- 3 The needle cannot change position because it is always securely clamped
- 4 It is finely balanced to facilitate handling
- 5 During suturing, clamping and unclamping are eliminated
- 6 The needle may be quickly set at eight different angles
- 7 Rethreading of needles is eliminated

It is of interest to note that the patient made the diagnosis himself before he reported to the medical officer, and he states that the present lesion is quite similar to the previous two, except that they have all been at different sites on the penis.

COMMENT

Moore's² criteria for probable second infection are (1) the proof of the original infection, either serologically or by dark field examination, (2) the development of a dark field positive lesion following adequate treatment, at an area different from that of the original infection and (3) negative serologic reaction at the time of the second lesion and development later of a positive serologic reaction or secondary symptoms. Stokes¹ also lists the criteria of reinfection and again mentions that the second chancre must be in a different site and lymph drainage from the first. Unfortunately the three lesions in this case were penile and so the question of a monorecursive relapsing infection arises. The argument for reinfection here is the adequate treatment over long periods and the persistently negative Kahn reactions changing to 4 plus after development of the new chancre plus the fact that 90 per cent of monorecurrences are said to occur in the first two years of the infection. In the second infection the treatment should probably not be called adequate, and so the question of relapse is most important when the classification of the third chancre arises. Here again the negative serologic reaction becoming 4 plus within five weeks and of course the history of venereal contact with a prostitute are on the side of reinfection. That the three lesions were all penile favors relapsing disease rather than reinfection. But otherwise the evidence favors reinfection.

THE PRESENT STATUS OF THE INFLUENZA PROBLEM

CLINICAL LECTURE AT ATLANTIC CITY SESSION

FRANK L. HORSFALL, JR., M.D.
NEW YORK

Almost ten years have passed since the first human influenza virus was discovered, and there would be now no great difficulty in enumerating a long series of significant developments which have resulted from the many careful investigations of influenza carried out in the last decade. To do this, however, would place the present status of the influenza problem in a false light, since positive knowledge would be overemphasized and lack of knowledge considerably neglected. This seems a proper time and an unusual opportunity to attempt a brief appraisal both of those things which are known and of those which are not known about influenza.

As is so frequently true in investigative work, each of the major advances made in the development of a more complete understanding of influenza has left in its wake a number of unsolved problems. At the present time the more significant of these appear to be (1) incomplete information as to the cause of influenza, (2) inadequate criteria for the clinical differentiation of different etiologic varieties of the disease, (3) insufficiency of available prophylactic measures and (4) lack of effective therapeutic procedures. It seems obvious that satisfactory solutions to all four of these matters

could provide the means whereby influenza would cease to be a problem. That these means are not yet available will become apparent as the present status of information concerning influenza is reviewed.

The clinical syndrome called influenza can be divided into three epidemiologic forms since each manifests certain characteristics which are distinctly different from the others. In the accompanying table is shown a classification of the forms of human influenza which seems to be in accord with what is now known of the condition. The three main forms are (1) the pandemic, (2) the epidemic and (3) the endemic.

PANDEMIC INFLUENZA

Pandemic influenza appears to have recurred at intervals for many centuries. It has been suggested that the disease reappears in predictable cycles, but a review of the available data indicates that the seven pandemics of the last century and a half were separated by varying periods of from three to forty-two years. In short, they did not occur with any regularity at all.

Perhaps the most important problem in the whole field of influenza is the nature of the causal agent or agents responsible for the pandemic form. Despite a tremendous amount of investigative work during the 1918-1919 outbreak there is no direct information concerning the cause of pandemic influenza. A number of astute hypotheses have been put forward and many workers think it possible that one or another virus may have initiated the infection. However, it should be emphasized that the cause of pandemic influenza is not yet known.

Bacterial infection of the respiratory tract occurred with considerable frequency during the 1918-1919 outbreak and seems to have contributed to the fatal issue in those cases in which death occurred. No single bacterial species was found in all cases, in some geographic areas streptococci were more common than *Hemophilus influenzae* while in others staphylococci were more frequently found than pneumococci in the consolidated lungs of fatal cases.

It seems likely that the sulfonamide drugs and the various specific antisera which are now available might be highly effective in combating bacterial infections of the respiratory tract should another pandemic occur in the future. Even in the absence of knowledge as to the cause of the pandemic form there is good reason to think that the fatalities due to bacterial infection could be materially decreased by the use of modern specific antibacterial therapy.

EPIDEMIC INFLUENZA

Epidemic influenza appears to be a much milder and less severe illness than the pandemic form. During the past decade the more extensive outbreaks of the epidemic condition have tended to occur during the winter months of odd numbered years, although there have been exceptions to this rough rule and in the tropics the illness has occurred often during the summer months.

There is now good evidence that there are at least three distinct and different etiologic varieties of epidemic influenza. The causal agent responsible for the first established variety was discovered in 1933 by Smith, Andrews and Laidlaw¹ in England. This agent is now termed influenza A virus, and clinical infection by it results in a disease which is called influenza A. The virus in the absence of bacteria causes a disease

¹ Smith, Wilson, Andrews, C. H. and Laidlaw, P. P. A virus obtained from influenza patients. *Lancet* 2: 66 (July 8) 1933.

resembling influenza in ferrets and is infectious also for mice, chick embryos and hamsters. In susceptible human volunteers the intranasal instillation of the virus is followed in from twenty-four to forty-eight hours by an illness which has practically all characteristics of naturally contracted influenza.

Classification of Forms of Human Influenza

Epidemiologic Forms	Virologic Varieties	Causal Agents	Occurrence of Bacterial Infections
Epidemic	Unknown	Not known	Common
Epidemic	Influenza A	Influenza A virus	Rare
Epidemic	Influenza B	Influenza B virus	Rare
Epidemic	Influenza Y	Undetermined	Rare
Endemic	Unknown	Not known	Common

The virus usually can be obtained from the nasopharynx of patients with influenza A during the first week after onset and has been found only rarely at later periods.¹ It has not been found in the upper respiratory tract of normal persons nor has it been shown to be present in persons with other acute respiratory diseases as for example the common cold, pneumococcal pneumonia and primary atypical pneumonia.⁴ It has not been demonstrated in the blood stream during influenza A and probably does not cause a systemic infection. The available evidence indicates that the agent is capable of multiplying only in the cells lining the respiratory tract. Although influenza A virus is capable of causing a severe and fatal pneumonia in ferrets and mice there is no evidence that it does so of itself in man. On the whole in cases of influenza A studied during the last nine years surprisingly few secondary bacterial infections have developed and in previously healthy persons postinfluenza pneumonia has been encountered only in exceptional instances.

During convalescence from influenza A there occurs a pronounced antibody response against the virus. This reaches maximum titer at about two weeks,⁴ and by comparing the antibody levels of two serums taken in the first few days and fourteen or more days respectively after onset it is possible to determine whether or not infection by influenza A virus occurred.

Influenza B virus was discovered by Magill⁶ and by Francis⁷ independently in 1940. Clinical infection by this agent results in a disease termed influenza B. Cases of influenza B are very similar to if not identical with cases of influenza A, and it has not yet been possible to differentiate between these two diseases on clinical grounds. However, influenza B virus and influenza A virus do not cross immunize against each other, and all the available evidence indicates that they are immunologically distinct and different agents.⁶

Influenza B virus is also infectious for ferrets, mice, chick embryos and hamsters. It can be obtained usually

from the nasopharynx of patients with influenza B during the first few days of illness and, like influenza A virus appears to be strictly pneumotropic and does not cause a systemic infection. As far as is known this virus has not caused pneumonia in human beings. As in the case of influenza A, there is very little evidence that influenza B is followed by secondary bacterial infections of the respiratory tract.

Following influenza B there develops a definite antibody response against the virus.⁷ It should be emphasized however, that this disease does not cause an increase in antibodies against influenza A virus, nor does influenza A result in the production of antibodies against influenza B virus. Even in the natural disease in man therefore, these two infectious agents give evidence of being entirely distinct immunologically, and it is possible by comparisons of antibody levels in the serum during the acute phase and convalescence to determine whether infection by one virus or the other, or neither, has occurred.⁹

Unfortunately not all patients with epidemic influenza can be shown to have been infected by one or the other of the two known human influenza viruses, and there is reason to think that there may be other agents as yet undetermined, which are capable of causing this illness. Epidemic influenza of unknown cause in which no evidence was obtained of infection by either influenza A or influenza B viruses has been called influenza Y.¹⁰ It has not been possible on clinical grounds to differentiate influenza Y from either influenza A or influenza B, indeed as will be shown later, examples of all three etiologic varieties of epidemic influenza have sometimes been encountered in a single outbreak of the illness.

ENDEMIC INFLUENZA

Endemic influenza, or sporadic grip, is that all too common acute febrile ailment which affects large numbers of persons during each winter. The more closely

Chart 1—Etiologic varieties of epidemic influenza during 1940-1941¹⁰

cases of this condition are studied the greater is the similarity observed between this clinical syndrome and that present in cases of epidemic influenza. In fact, there do not seem to be any symptoms or signs which serve to differentiate clearly between individual cases of endemic and epidemic influenza. It is only because of the similarity of the manifestations of the symptom

complex that the endemic illness is included in this classification of human influenza

The cause or causes of endemic influenza are not yet known. There is, however, evidence that the illness is not caused by infection with either influenza A or B viruses.⁴ Secondary bacterial infection of the respiratory tract, particularly of the paranasal sinuses or bronchi, follows endemic influenza with considerable frequency, and any one of a number of bacterial species may be responsible for these sequelae.

ETIOLOGIC STUDIES

In chart 1 are presented graphically the results of etiologic studies of 1,276 cases of epidemic influenza which occurred in twelve separate outbreaks during 1940 and 1941.¹⁰ The percentage of cases of influenza A, influenza B and influenza Y in each epidemic is shown. The very small proportion of cases which in some epidemics showed an increase in antibodies against both viruses is also shown.

It will be observed that cases of influenza Y were found in all but two epidemics, whereas cases of influenza B were encountered in only five of the epidemics. Cases of influenza of unknown cause or influenza Y,

Chart 2—Relative incidence of influenza in control and vaccinated groups during 1940-1941 epidemic¹

occurred in each epidemic and varied from 11 per cent in one to 80 per cent in another, with an average incidence of 30 per cent. It seems apparent from these data that in a given epidemic of influenza cases of all three etiologic varieties of the illness may occur. In three of these epidemics this was found to be the case. Because of these findings it has been suggested that epidemics of influenza may have diverse causes and that cases presenting a single symptom complex in one epidemic may result from infection by any one of at least three distinct infectious agents, of which two are known.¹⁰

Effective prophylaxis against infectious disease is usually dependent primarily on accurate information regarding cause. In the case of epidemic influenza the agents responsible for influenza A and influenza B are known and numerous attempts have been made to produce active immunity against the former disease in man by means of vaccines containing influenza A virus.

Unlike many other virus diseases, an attack of influenza A does not appear to result in enduring immunity against this illness. It has been known for some time that the high antibody levels against the virus which are commonly found during the first month of convalescence gradually decline and tend to approximate preinfection levels in from six to twelve months.

Recently it was shown that repeated attacks of influenza A could and did occur in the same persons with intervals no longer than two years between attacks.¹¹ These findings tend to cast much doubt on the possibility that persistent active immunity against this disease could be established by present methods of immunization.

In the past year five independent studies of the effectiveness in man of vaccines containing influenza A virus have appeared.¹²⁻¹⁶ The results of these studies are presented graphically in chart 2. In each investigation groups of volunteers were given vaccine subcutaneously while other groups were left unvaccinated as controls. Epidemic influenza, chiefly influenza A, occurred in these subjects from one week to four months after the vaccine was given and consequently in most instances there had been adequate time for the development of maximum antibody response to the virus. The relative incidence of epidemic influenza in the control and vaccinated groups is shown. The percentage incidence in each group is also given, as well as the total number of cases in both groups. It will be observed that the results varied appreciably and while one study showed a reduction in incidence of 47 per cent among vaccinated persons,¹⁷ another study revealed no significant reduction whatever.¹¹ On the average these reports indicate that there were about two thirds as many patients with epidemic influenza in the vaccinated groups as there were in the unvaccinated group. Although this reduction in the incidence of the disease following vaccination may be statistically significant, it seems obvious that the average extent of immunity induced by this procedure was insufficient to make of it a practicable prophylactic measure. Moreover recent studies indicate that the duration of the somewhat increased resistance which may follow vaccination with influenza A virus is short and that the maximum effect persists for only about one month.¹⁴

Knowledge of the causation of two varieties of epidemic influenza has not yet been of assistance in the development of specific therapeutic measures. As in the case of most virus diseases, once symptoms have developed the course of the illness is but little if at all altered by therapeutic procedures. It is obvious that general and symptomatic therapy judiciously used achieves considerable relief for the patient, but even so the disease runs its full course. Although a few claims have been made for the efficacy of one or another of the sulfonamide drugs in experimental infections with influenza A virus, these have not been substantiated and at the present time none of the available drugs are known to influence favorably the course of the disease either in experimental animals or in man.

Finally it seems evident that the commonness with which one or another of the various forms of influenza

occurs and the very large number of persons who are temporarily incapacitated each year by the symptom complex make it an illness about which it is important to have more information. At the present time evidence of the nature of the infectious agents responsible for the pandemic and endemic forms would be of great value, as would such information regarding epidemic influenza of unknown cause. It may be that future investigations will furnish procedures by means of which it will be possible effectively to treat or preferably to prevent certain varieties of influenza although so far these problems remain unsolved.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
ALSTIN F. SMITH, M.D., Acting Secretary

STATUS OF RACEMIC EPINEPHRINE FOR ORAL INHALATION

VAPONEFRIN (Vaponefrin Company),
ASTHMANEFRIN (Asthmanefrin Company),
SOLUTION (or INHALANT) A and NEOSOL
(Neosol Company, Inc.),
SOLUTION (or INHALANT) N (Nephron Company)
NOT ACCEPTABLE FOR N N R

For some time there has been marketed a solution of syn thetic racemic epinephrine hydrochloride used with an atomizer for oral inhalation in the treatment of asthma and/or hay fever. The solution is promoted directly to the public and to the physician under different trade names by several distributors, with claims that tend to imply a superiority of synthetic racemic epinephrine (l-epinephrine and d-epinephrine in equal proportions) over epinephrine U S P (pure levo rotatory epinephrine). Some of the product and concern names which have been used to market the preparation are as follows: Asthmanefrin (Asthmanefrin Company, Portland, Ore. or Upper Darby, Pa.), Vaponefrin (Vaponefrin Company, Upper Darby, Pa.), Solution A Inhalant A and Neosol (Neosol Company, Inc. Upper Darby, Pa.) Solution N and Inhalant N (Nephron Company, Tacoma, Wash.)

Because of inquiries which have been received regarding the solution and the variety of names under which it is marketed the Council felt that it was necessary to investigate the claims made for the products in order to make available an informative report to the medical profession. Information available to the Council indicates that Vaponefrin (Vaponefrin Company) is sold to physicians, whereas the solution under the other names is or has been sold directly to the public, and that Asthmanefrin Vaponefrin and Neosol are identical products. In view of this, the Council believes it sufficient to focus particular attention on Vaponefrin, since it is sold to physicians.

Among the claims made for Vaponefrin which imply a superiority of racemic epinephrine over epinephrine-U S P occurs the statement that the U S P method of testing Vaponefrin has shown a somewhat stronger action than the 1:100 (1 per cent) solution of epinephrine hydrochloride. The latter preparation as described in New and Nonofficial Remedies is made from epinephrine-U S P (l-epinephrine) contained in the form of the hydrochloride in isotonic solution of sodium chloride as the vehicle. Except for the use of racemic epinephrine in place of epinephrine U S P and the absence of the antioxidant, 0.1 per cent of sodium bisulfite (which would not be so essential in the more stable racemic form), the composition of Vaponefrin is similar to that of the N N R preparation. However, since no statement of the concentration of Vaponefrin is made in the labeling or is included with the information concerning the product sent to physicians it is impossible to evaluate the claim for

its greater potency, even when the physician is aware that d-epinephrine is much less active than l-epinephrine and that a racemic mixture would therefore have little more than half the activity of the pure levorotatory epinephrine listed in the U S Pharmacopeia. The comparative inactivity of the dextro isomers of certain drugs is well established, and in the case of epinephrine various investigators¹ have shown that, while d-epinephrine has qualitatively the same action, it is quantitatively only one twelfth to one eighteenth as potent as the l-epinephrine. Cori and Welch² conveniently indicate the average of these results when they point out that naturally occurring l-epinephrine is approximately fifteen times as active as the dextro isomer.

In the information sent to physicians the claims made for Vaponefrin are stated to represent the pertinent findings of physiologic research recently done on the product by James C. Munch, Ph.D., and are accompanied by reprints of two published papers concerning studies made with the solution by this and other investigators. In the paper by Munch, Gattone and Pratt³ it is reported from observations on animals that the pressor potency of vaponefrin base (racemic epinephrine) was found to be about two thirds the pressor potency of epinephrine base (levo-epinephrine) and that by properly modifying the concentrations the same intensities of pressor response were readily obtained. Other observations indicated that Vaponefrin solutions were more stable than epinephrine solutions when stored under similar conditions. In the other paper by Richards, Barach and Cromwell⁴ data are tabulated for the comparative effect on vital capacity of 1:100 solutions of epinephrine hydrochloride, neosynephrine hydrochloride, epinephrine and neosynephrin hydrochlorides combined, Vaponefrin, and neosynephrin hydrochloride and Vaponefrin combined, administered by a technique of continuous vaporization with oxygen (1 cc of solution for three to ten minutes) in patients with various types of pulmonary disease. Although their results with this method in bronchial asthma indicate that Vaponefrin is almost two and one half times more effective than either the epinephrine or neosynephrin hydrochloride solutions the authors point out that the data obtained provide no constant indication as to the relative effectiveness of the various solutions, but that the 1:100 solution of epinephrine hydrochloride and the Vaponefrin solution usually had the strongest action. The authors propose the use of the continuous inhalation technique in very ill or dyspneic patients because it eliminates the effort required to manipulate the hand bulb atomizer and they did not find that toxic side effects were increased by this technique. Their paper includes the statement "Vaponefrin solution, a proprietary product whose composition is stated by the manufacturer to contain 1 to 100 epinephrine, and 0.5 per cent chlorbutanol." Apparently the quoted portion of the authors' statement applies to information previously furnished by the distributor, since more recent information available in the files of the Council office reveals no declaration of the dilution or concentration.

Obviously the results reported in the two distributed reprints are indirect contradiction in that the one shows the potency of the product to be less than that of solutions of epinephrine (U S P) of the same concentration whereas the other indicates the potency of Vaponefrin (1:100) to be more than twice that of the solution of epinephrine in the same dilution as measured in bronchial asthma by differences in vital capacity. Apparently in the latter study the investigators made no attempt to analyze the Vaponefrin used.

In view of this it was suspected that the claim for stronger action of Vaponefrin might be explained on the basis that the

solution contains a greater concentration of racemic epinephrine hydrochloride than the 1 per cent solution of l-epinephrine hydrochloride represented by Solution of Epinephrine Hydrochloride 1 100-N N R. Accordingly, the A M A Chemical Laboratory was requested to examine a specimen of Vaponefrin. On analysis it was found to contain approximately 23 mg of optically inactive (racemic) epinephrine per cubic centimeter of the solution. This corresponds roughly to a 1 40 dilution or 25 per cent concentration when expressed in terms of the hydrochloride and readily explains the distributor's statement that "Vaponefrin has shown a somewhat stronger action than 1 100 Epinephrine Hydrochloride solution" when it is remembered that racemic epinephrine is only slightly more than half as active as the official levorotatory isomer.

Other claims made for Vaponefrin include statements that it is a highly purified product resulting from chemical syntheses whereas, part of the Epinephrine on the market is obtained by extraction from glandular sources and is not readily purifiable, that "It is the hydrochloride and not the free base", that "it is an optically inactive racemic product and therefore contains the dextro and the laevo isomers," and that "Epinephrine U S P is the laevo-methylaminoethanolcatechol." Such statements are apparently intended to inspire the confidence of the unwary physician, and, while entirely correct as isolated facts in themselves, they do not tell the whole story and tend to place the official levo epinephrine—which is actually more purified from the standpoint of epinephrine activity—in an unfavorable light. As has already been pointed out, the N N R 1 100 solution of epinephrine U S P is also in the form of the hydrochloride.

The distributors of Vaponefrin and of some of the other racemic epinephrine solutions have apparently found it profitable to withhold the declaration of concentration of the active ingredient. However, according to a reliable source of information, the lay promoted product Inhalant N (Nephron Company) is labeled as containing 25 per cent of synthetic epinephrine (racemic) and the product Asthmanefrin (Asthmanefrin Company) has been found to be essentially a 2 per cent solution of racemic epinephrine. Claims which have been made for the latter product are essentially the same as those made for Vaponefrin except for the additional statements that, in comparison to epinephrine U S P, Asthmanefrin is more stable and may change color without detectable loss of potency and that its use is followed by virtually no side actions, probably because of its lesser toxicity or of the fact that by the method of administration the clinical effect on the bronchioles is produced before any significant action develops on the blood pressure. The fact that the racemic compound is more stable is not of great significance in view of the fact that the official l-epinephrine is sufficiently stable when protected against heat, light and air—particularly when protected against deterioration by the addition of a suitable antioxidant. Obviously, the claim that the solution has less side action or may be less toxic is not accurate from the standpoint of epinephrine activity in view of the fact that a 2 per cent solution of racemic epinephrine (containing 1 per cent each of l-epinephrine and d-epinephrine) would be actually a trifle more active (about one fifteenth) than a 1 per cent solution of l-epinephrine. The point made that Asthmanefrin acts on the bronchioles before significantly affecting the blood pressure is equally applicable to 1 100 solution of l-epinephrine hydrochloride. Studies with the latter solution reported by Galgiani and his associates⁵ indicate that the amount usually administered by oral inhalation is too small to produce systemic effects of the drug as measured by the blood pressure and pulse. In connection with Asthmanefrin reference is also made to the report by Richards, Barach and Cromwell⁴ and to a paper by Eckman and Barach.⁶ Neither report includes mention of the product. The paper by Eckman and Barach contains only one section, at the end of which might be considered pertinent, and this consists simply of illustrated directions for the use of a nebulizer set with an oxygen tank.

for the administration of vaporized solutions of Adrenalin (the hydrochloride of epinephrine U S P) and neosynephrin hydrochloride by oral inhalation.¹ Although the Asthmanefrin Company indicated that this report includes a description of a VapoEfrin vaporizer (also described by the Vaponefrin Company as the Physicians Allergic Unit) and the assertion that it is the most efficient appliance of this nature available, the nebulizer set pictured in the paper is not identified by any name and does not correspond to the hand bulb vaporizer illustrated in the information supplied by the Vaponefrin Company. Furthermore, the authors of this paper make no statement concerning the efficiency of the apparatus. Such misuse of published information cannot be too strongly condemned.

The Richards' report includes statements to the effect that the Vaponefrin model vaporizer produces a somewhat more voluminous vapor stream than a 'Vapco' model but contains no data to show on what evidence this observation is based. While the Council believes the efficiency of apparatus used in vaporizing epinephrine solutions for oral inhalation in the symptomatic treatment of bronchial asthma may influence the effectiveness and the required dosage of the drug by increasing the subdivision of the mistlike droplets of solution suspended in the inhaled vapor (thereby enlarging the total surface area of contact) the quality or quantity of vapor produced should not be offered to explain the apparent differences in the activity between racemic epinephrine solutions and solutions of l-epinephrine unless allowance is made for the difference in potency between the two forms of the drug and in the concentration of the solution. Controlled observations using the same type of solution are required to demonstrate that a particular model of vaporizer is more effective than others. Differences in nebulizers or vaporizers as well as the duration of application may well explain why dilutions of l-epinephrine hydrochloride of twice (1 50) or even one half (1 200) that of the more widely used strength of 1 100 are sometimes more effective for certain patients with asthma. Previously reported evidence that the latter dilution is best suited for oral inhalation in the average case forms the basis for the acceptance of this solution for that purpose by the Council. The Council holds that it is absolutely essential that such treatment be instituted under the supervision of the physician and that the amount of the solution used should not exceed the minimum required for effective relief. It is therefore obviously more preferable to prolong the inhalation of the 1 100 dilution than to employ more concentrated solutions when a larger dose is needed. Of course this strength should not be confused when the 1 1000 solution of epinephrine hydrochloride U S P is used for injection.

The direct sale to the public of any type of epinephrine solution is to be condemned. Physicians would be well advised to recommend the use of officially recognized solutions of the drug rather than to rely on the misleading statements made by the distributors of racemic epinephrine products. The Council on Physical Therapy of the American Medical Association regularly examines apparatus such as nebulizers and unless the vaporizer sold with Vaponefrin has been critically examined by an equally competent authority, the physician had better rely on the similar devices which have been accepted by that Council. Certainly, from the evidence just reviewed, the reported greater effectiveness of Vaponefrin is better explained by the difference in concentration of the solution and the form of epinephrine present rather than by the possible greater efficiency of the vaporizer sold with the solution. If this vaporizer does deliver more vapor, the larger dose administered is obviously another reason for its stronger action. Given the same equipment and duration of application, the therapeutic effect of a 1 per cent (1 100) solution of epinephrine hydrochloride is essentially the same as that of a 2 per cent (1 50) solution of racemic epinephrine hydrochloride.

The Council voted to publish the foregoing report in order to inform the medical profession concerning the status of racemic epinephrine solutions for oral inhalation and the unwarranted disparagement of epinephrine U S P and solution of epinephrine hydrochloride 1 100-N N R by the distributors of Vaponefrin and similar products sold under different names.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONTRIBUTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A LIST OF THE RULES BY WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

ALSTON I. SMITH, M.D., Acting Secretary

ZEPHIRAN CHLORIDE—A mixture of alkyl dimethyl benzyl ammonium chlorides having the general formula $C_nH_{2n+1}N(CH_3)_2RCl$ in which R represents a mixture of alkyl radicals from C_{11} to C_{15} .

Actions and Uses—Zephiran chloride when employed in solutions of the proper dilution is an effective relatively non-irritating surface disinfectant which is germicidal for many pathogenic nonsporulating bacteria and fungi after several minutes exposure. Solutions of zephiran chloride have low surface tension and possess detergent, keratolytic and emulsifying actions properties which favor penetration and wetting of tissue surfaces. Solutions of ordinary soaps which are anionic detergents in concentrations as low as 0.1 per cent may reduce the germicidal activity of zephiran chloride which is a cationic detergent unless its application is preceded by careful rinsing of soap cleansed areas to be disinfected. Alcohol diminishes the ionization of ordinary soap solution so that the inactivating chemical union of soap with the disinfectant is to some extent prevented. For this reason the application of alcohol 70 per cent (by volume) may well follow the use of the soap and water scrub-rinse procedure as carried out in the usual preoperative technique for preparation of the intact skin before application of the disinfectant. Obviously under such circumstances the use of the tincture is to be preferred the use of the aqueous solution being restricted to those regions where soap is not ordinarily employed or where alcohol would produce irritation. The careful rinsing of soap also applies to the disinfection of soap cleansed inanimate objects such as surgical instruments.

Solutions of zephiran chloride are said to have an emollient action and to be relatively nonirritating in effective concentrations. Solutions are of comparatively low toxicity under the conditions of use for which they are recommended. Rabbits tolerate from 3 to 5 cc by mouth or 1.2 cc subcutaneously or intraperitoneally per kilogram of body weight of a 10 per cent aqueous solution. Application to the skin of these animals of various concentrations show that a 1 per cent solution is the highest concentration that may be allowed to remain in contact for twenty-four hours without producing irritation. As with other types of disinfectants zephiran chloride has little sporicidal activity and its germicidal potency is greatly reduced by serum. It should be kept in mind that phenol coefficient values as a basis for comparing the relative efficacy of germicides is subject to erroneous interpretation when applied to conditions of actual use.

Zephiran chloride is suitable for general use in the prophylactic disinfection of the intact skin and mucous membranes and in the treatment of superficial injuries and infected wounds in solutions ranging in concentration from 1/40,000 to 1/1,000. It is also used for the preservation of sterilized surgical instruments and rubber articles during storage. Sodium nitrite 0.5 per cent is added to zephiran chloride solutions for the storage of metal instruments to prevent corrosion.

Dosage—For the preoperative disinfection of the unbroken skin or the treatment of superficial injuries and fungous infections zephiran chloride tincture 1/1,000 (tinted or stainless according to preference) is recommended. Zephiran chloride solution is employed in concentrations of from 1/10,000 to 1/2,000 for the preoperative disinfection of mucous membranes and denuded skin, from 1/5,000 to 1/2,000 for instillation and irrigation of the eye or vagina and from 1/10,000 to 1/5,000 for widely denuded surfaces. For urinary bladder and urethral irrigation a concentration of not more than 1/20,000 of the aqueous solution is recommended, for retention lavage of the bladder, a concentration not to exceed 1/40,000 should be used. For therapeutic disinfection of deep lacerations the undiluted 1/1,000 aqueous solution may be employed but for the irrigation of infected deep wounds, concentrations not to exceed 1/3,000 should be used. For the treatment of infected widely denuded areas with wet dressings, the aqueous solution should be used in concentrations of 1/5,000 or less.

For the sterile storage of metallic instruments and rubber articles, zephiran chloride solution 1/1,000 is used. For the disinfection of operating room equipment a 1/5,000 concentration of the solution may be employed.

Tests and Standards—

Zephiran chloride occurs as a colorless or slightly yellow gelatinous material containing from 10 to 20 per cent of water possessing an aromatic odor and a very bitter taste. It is miscible in all proportions with water, alcohol and acetone, slightly soluble in benzene and insoluble in ether. The aqueous solution is slightly alkaline to litmus. Two cc portions of a 1 per cent aqueous solution yield only precipitates with diluted nitric and sulfuric acids, white precipitates with solutions of mercury salts and a gelatinous precipitate with soap solution.

To 2 cc of a 1 per cent solution of zephiran chloride add 2 cc of ethanol, 0.2 cc diluted nitric acid and 0.5 cc of silver nitrate solution. A curdy white precipitate results which is insoluble in diluted nitric acid but soluble in diluted ammonium hydroxide. Heat approximately 0.1 Gm of zephiran chloride with a small piece of metallic sodium in a small soft glass test tube. Break the red hot tube in 10 cc of distilled water, filter and to the clear filtrate add a few drops of 10 per cent ferric sulfate solution. Boil for one minute, add 2 drops of ferric chloride solution and acidify with diluted hydrochloric acid. A finely divided blue precipitate forms. Dissolve approximately 0.2 Gm of zephiran chloride in 1 cc of sulfuric acid, add 0.1 Gm of sodium nitrate and heat on a steam bath for three minutes. Cool the solution, dilute to 10 cc with water, add 0.5 Gm of zinc dust and warm for five minutes. Decant 2 cc of the clear liquid, add 1 cc of a 5 per cent sodium nitrite solution, cool in ice water and add 1 cc of G salt dissolved in ammonium hydroxide, a deep orange red color results.

Transfer approximately 1.5 Gm of zephiran chloride accurately weighed to a wide mouthed weighing bottle and dry in an oven at 100° C for twelve hours, cool and weigh. Determine the moisture content of the original according to the method of Smith and Bryant (*J. Am. Chem. Soc.* 57:841, 1935) as follows: Prepare approximately 1.5 molar acetyl chloride by dissolving 11.8 cc of acetyl chloride in toluene to make 100 cc. Transfer 10 cc of this solution to a glass stoppered flask, cool for one minute in ice water and add 1 cc of pyridine and approximately 0.8 Gm of zephiran chloride accurately weighed. Shake the mixture and after allowing to stand five minutes, add 1 cc of freshly dried ethanol followed in five minutes by 25 cc of absolute ethanol. Shake the solution and after ten minutes titrate with 0.5 normal sodium hydroxide using phenolphthalein as an indicator. Make a blank determination on the reagents and subtract it from the determination of the unknown.

Dissolve approximately 5 Gm of zephiran chloride accurately weighed in water to make 100 cc of solution. Transfer a 10 cc sample to a 100 cc flask, add 5 cc of buffer solution (260 Gm of sodium acetate and 280 cc of 30 per cent acetic acid to make 1 liter) and 50 cc of 0.020 normal potassium ferrioxalate. Dilute to 100 cc, mix well and allow to stand for one hour. Filter the mixture through paper and discard the first 20 cc. To the next 50 cc, add 5 cc of 10 per cent potassium iodide solution and 5 cc of diluted hydrochloric acid. After one minute add 10 cc of 10 per cent zinc sulfate solution and titrate with 0.01 normal sodium thiosulfate using starch as an indicator. The weight of zephiran chloride calculated by the formula $(50 - 0.01 \times N \times Na_2S_2O_3) \times 0.02205$ is not less than 97 per cent nor more than 100 per cent of the original calculated from the dry weight.

Transfer approximately 0.1 Gm of zephiran chloride accurately weighed to a small digestion flask, add 2 cc sulfuric acid and 0.05 Gm of metallic selenium. Digest the mixture until decomposition is complete, dilute to 15 cc, make alkaline with sodium hydroxide solution, dilute into 0.2 normal acid and titrate the excess acid with 0.02 normal alkali using methyl red as indicator. The nitrogen content is not less than 3.7 nor more than 3.85 per cent of the dry weight.

Transfer a sample of zephiran chloride accurately weighed to a 150 cc beaker and dissolve in 60 cc of 40 per cent ethanol. Add 4 cc of diluted nitric acid and an excess of 15 per cent silver nitrate solution. After an hour filter the precipitated silver chloride, wash well with 40 per cent ethanol and dry at 105° C. The chloride content calculated to the dry weight is not less than 9.55 nor more than 9.7 per cent. Transfer approximately 1 Gm of zephiran chloride accurately weighed to a platinum dish, ignite until constant weight is attained, the ash is less than 0.1 per cent.

AMERICAN MEDICAL ASSOCIATION 1943 ANNUAL SESSION CALLED OFF BY BOARD OF TRUSTEES

The American Medical Association will not hold its ninety-fourth annual session scheduled to convene in San Francisco in 1943. This is the third time in the history of the Association that an annual session has been canceled. In 1861 the session was postponed for a year because of the outbreak of the war between the states, and in 1862 it was again postponed for a year because of the demands of the war on the medical profession. The House of Delegates, the Board of Trustees, the scientific councils and the officials of the Association will be called into session to deal with the affairs of the Association, particularly the many wartime responsibilities being borne by the medical profession.

The tremendous demands on the medical profession of the United States in association with the war, including the provision of physicians for the armed forces, for the care of veterans, for industry and for the care of the civilian population, has caused the Board of Trustees of the American Medical Association to give special consideration to problems associated with the holding of the session.

The annual session of the Association with the attendance usually assembled on such occasions would take away from medical practice at the time from six to ten thousand doctors, together with many persons in associated professions concerned with the Scientific Exhibit, the Technical Exhibit and other features. The demands on the time of physicians are already innumerable. Moreover, the holding of the session in San Francisco would involve transportation in large part from other sections of the country, calling particularly on the railroads and also on all other means of transportation.

The Board of Trustees has given special attention to statements issued by the Office of Defense Transportation, the War Department, the Navy Department and other governmental agencies concerning the holding of conventions.

The primary consideration involved particularly relating to the annual session is the call that would be made on the time and work of physicians. Already the utmost that the medical profession can do to provide medical services for the Selective Service System, the Army, the Navy, the Public Health Service, industry and the civilian population is in some places being severely strained. These demands will no doubt be intensified by next June.

While the Scientific Assembly and the Scientific and Technical exhibits will not be held in 1943, the many significant problems of the medical profession occasioned by the war, particularly such as concern the provision and distribution of physicians and the provision of medical service, are of such moment that the House of Delegates, the Board of Trustees, the various scientific councils and officials will be called into session in June 1943. This meeting will be held in Chicago in order to place the minimum stress on the time of the physicians concerned and on the transportation facilities of the nation.

In making these decisions the Board of Trustees has kept in mind the solemn obligation entered into by the House of Delegates and the Board of Trustees of the American Medical Association to give to the nation every possible contribution that the Association can make to aid the war effort.

FORCED SPINAL DRAINAGE IN ACUTE POLIOMYELITIS

Investigation of the therapeutic value of "forced spinal drainage" (the so-called Retan technic) has been made by Kramer and his colleagues¹ of the Bureau of Laboratories, Michigan Department of Health. They have applied this method of treatment to experimental poliomyelitis in monkeys and report negative results.

In 1919 Weed and McKibben² showed that in laboratory animals intravenous injection of large volumes of hypotonic salt solution is followed by a prolonged and profound increase in cerebrospinal pressure associated with distention of the perivascular and perineural spaces. Kube³ of the New York Neurological Institute afterward found that this increased pressure and hydration can be prevented by a parallel release of cerebrospinal fluid through lumbar or cistern puncture. He suggested the possible therapeutic value of "forced spinal drainage" brought about by a simultaneous intravenous injection of hypotonic salt solution and lumbar puncture. Theoretically this should cause an interstitial lavage or "washing out" of micro-organisms and exudates from the depth of the central nervous

¹ Kramer S. D., Geer H. A. and Himes A. T. *J. Immunol.* 44: 175 (July) 1942.

² Weed L. H. and McKibben P. S. *Am. J. Physiol.* 48: 512-531 (May) 1919.

³ Kube L. S. Intracranial Pressure Changes During Forced Drainage of the Central Nervous System. *Arch. Neurol. & Psychiat.* 16: 319 (Sept.) 1926. Forced Drainage of the Cerebrospinal Fluid in Relation to the Treatment of Infections of the Central Nervous System, *ibid.* 19: 997 (May) 1928. *Brain* 51: 244 (June) 1928.

tissues. In his hands intravenous injection of large amounts of hypotonic salt solution was well tolerated by both man and experimental animals.

Five years later Kubie and Retan⁴ reported their clinical experience with this method, with allegedly beneficial results in syphilis of the central nervous system, pyogenic meningitides, encephalitis, chorea and tuberculous meningitis. Since then the suggested technique has been simplified by Retan,⁵ who reported equally beneficial effects on omitting the accompanying lumbar or cistern puncture. His simplified technique consists in the continuous intravenous injection of approximately half isotonic solution of sodium chloride at the rate of 10 cc per pound hourly, the injection being given over periods of eight hours followed by a four hour rest period between treatments. An occasional lumbar puncture for diagnostic purposes was the extent of the external drainage. He suggested the desirability of a crucial test of the therapeutic value of this simplified technique in experimental poliomyelitis in animals, under which conditions adequate controls are possible.

This crucial test was undertaken by the research staff of the Michigan Department of Health. Preliminary tests showed that normal uninfected monkeys can withstand six to eight continuous eight hour intravenous injections with 0.375 per cent sodium chloride solution at the recommended rate (10 cc per pound, hourly) without serious symptoms or after-effects. Twenty-five monkeys were then infected by intracerebral injection of 0.5 to 1 cc of the supernate from a 5 per cent centrifuged poliomyelitis cord suspension, both highly virulent and relatively low virulent viruses being used. Eleven of the infected monkeys were given from one to five such treatments by the Retan technique, 14 infected monkeys serving as controls. In some cases the treatment was begun as soon as two hours after the intracerebral inoculation, in others it was delayed for twelve to twenty-four hours or even longer.

In a typical test group 4 monkeys were inoculated with equal doses of a low virulent virus. In 1 monkey intravenous injection of hypotonic salt solution was begun twelve hours after inoculation and continued with the recommended four hour rest periods till the animal had received eight treatments. This monkey developed typical paralysis on the sixth day and died on the tenth day, necropsy showing the characteristic histologic picture of experimental poliomyelitis. In a second infected monkey treatment was delayed for forty-eight hours. This animal died seven and one-half hours after the treatment was initiated, necropsy showing fluid in both the thoracic and the abdominal cavity, with a histologic picture compatible with experimental

poliomyelitis. Both nontreated monkeys developed typical paralysis between the seventh and the ninth day, from which both recovered. One control was killed two months later, microscopic examination revealing healing poliomyelitis. The other control monkey was still living at the time of their report.

In this typical series the Retan treatment appeared to be directly responsible for the rapidly fatal results in 1 monkey and hastened the development of paralysis and death in the second monkey. Similar deleterious effects were recorded with all other groups of inoculated monkeys treated. The investigators were therefore forced to the unavoidable conclusion that Retan therapy is without therapeutic value in acute poliomyelitis in monkeys.

In order to harmonize this failure with previously reported clinical successes, one might emphasize the generally accepted fact that poliomyelitis is due to an intracellular virus which is presumably transmitted from cell to cell mainly through axons or dendrites. Thus located, the virus would not be easily influenced by forced interstitial drainage. Most of the reported clinical successes have been with infections in which the causative agent exists in whole or in main in the extracellular tissue spaces. Thus located the organisms might be readily "washed out" by forced perivascular lavage. Crucial animal tests with these extracellular neurologic infections have not yet been made.

THE NEW AMERICAN MEDICAL DIRECTORY

The new Seventeenth Edition of the American Medical Directory is in the bindery. Never before has a new directory been so much in demand. The intensified activities of physicians, pharmaceutical manufacturers, insurance companies and the medical branches of the Army, Navy, Selective Service System and the Procurement and Assignment Service have made the need for an up to date medical directory especially urgent. The American Medical Directory is the only national medical directory of physicians published. It covers not only the United States but also Canada, Alaska, the Canal Zone, Hawaii, the Philippines and Puerto Rico.

The new Directory will show, as far as the information is obtainable, those physicians who had already joined the armed forces up to the time the forms were closed for printing. The medical officers of the Reserve Corps of the United States Army and the Army of the United States, of the Navy and the Naval Reserve, and of the National Guard on active duty are listed at their permanent home addresses followed by the symbols ∇ , ∇N , and ∇G respectively. The medical officers of the regular United States Army, Navy and United States Public Health Service are listed in the front section of the book according to rank, as in previous editions. However, for military reasons Army and

⁴ Kubie L. S. and Retan G. M. Forced Drainage of the Cerebrospinal Fluid. *J. A. M. A.* 101: 354 (July 29) 1933.

⁵ Retan G. M. The Development of the Therapeutic Use of Forced Perivascular (Spinal) Drainage. *J. A. M. A.* 105: 1333 (Oct. 26) 1935. *J. Pediat.* 11: 647 (Nov.) 1937. Intravenous Injection of Hypotonic Salt Solution Containing Sulfanilamide for Streptococcal Meningitis. *Am. J. Dis. Child.* 56: 483 (Sept.) 1938. *New York State J. Med.* 39: 1774 (Sept. 15) 1939.

Navy officers are listed in the geographic section of the Directory under Washington, D. C., instead of the station to which they have been assigned.

Other new information included in the Directory is the certification of 4,000 additional physicians as specialists by the various American boards. Data have been added on the new boards covering plastic surgery and neurologic surgery. The American Board of Internal Medicine now also certifies candidates in the medical subspecialties of allergy, cardiovascular disease, gastroenterology and tuberculosis. The American Board of Surgery now certifies specialists in the subspecialty of proctology.

The new Directory contains 201,272 names of physicians and 2,801 pages, or 126 pages more than the previous edition. Since the last edition 15,223 new names of recent graduates and physicians from abroad have been added and more than 72,114 changes of address have been made. Names dropped from the Directory number 8,656, principally on account of death.

The Directory may be divided into three parts. The first covers national and interstate information; the second lists information regarding hospitals and biographic data of physicians; and the third is the alphabetical index of physicians.

The first division includes data regarding the officers and the Constitution and By-Laws of the American Medical Association, histories of medical schools, medical libraries, journals, and the officers and members of special medical societies. A list of the members of the National Board of Medical Examiners and officers of the examining boards in the medical specialties, and also a list of approved internships, approved residencies and fellowships, government officers of the Army, Navy, Public Health Service, Veteran's Administration and the Indian Field Service appear in this section.

In the second section, or the body of the book, will be found a list of hospitals and physicians grouped by states. Under each state appear data regarding medical practice and digest of law, officers of examining boards, board of health, and state and county medical societies. Following this information will be found the list of hospitals, indicating the number of beds in each, the kind of institution and the name of the person in charge. Next comes the alphabetical arrangement by cities of the list of physicians, with biographic data as to year of birth, medical school and year of graduation, year of license, membership in special societies, residence and office addresses, and a special symbol if the physician is serving with the armed forces.

The third section of the book contains the names of physicians alphabetically arranged by surname, followed by the city and state under which detailed information regarding the physician may be found in the body of the book.

Here is information on how to use the Directory. On the front cover is a list of the states and the page number on which the information may be found. Open the Directory to any section. On the top of the pages are titles, guide words to indicate the data given on the pages. Once you have found the city, it is easy to look up the name of the physician because the names are arranged alphabetically. If you do not know the location of the physician and have only his name, you can refer to the alphabetical index for his city and state. A knowledge of the exact meaning of the symbols and abbreviations used is essential; study for a few minutes pages 6 and 7. Keep these page numbers in mind, mark them if necessary, and turn to them frequently until you are well acquainted with them, so that the entry after each name unfolds its full meaning. Many subscribers to the Directory do not familiarize themselves fully with the abbreviations and symbols and consequently do not appreciate, or use the full value of the Directory. Learn to use this book whenever you want facts concerning a physician not well known to you. What privileges or protection does the medical law of a state give? To what sanatorium can I send a patient? Who is the author of this article in my journal? Who is the physician who has called for consultation? All this and much other information on medical topics are arranged conveniently for reference in this new edition of the American Medical Directory.

Current Comment

MISLEADING INSURANCE ADVERTISING ON HEART DISEASE

According to a communication from the Better Business Bureau of Pittsburgh, "an insurance company" is disseminating literature stating that "a certain policy covers heart disease," where is the actual policy provides protection only against "aneurysm of the aorta." Any physician would know that this is misleading. Tabulations of the division of vital statistics of the Bureau of the Census indicate that there were 3,635 deaths due to aneurysm of the aorta reported in 1940. The probability of dying from aneurysm of the aorta is relatively small, as indicated by the death rate of 2.8 per hundred thousand of population. In comparison with the mortality from heart diseases, the number of deaths from aneurysm of the aorta is less than 1 per cent of the total deaths reported for the diseases of the heart. There were 385,191 deaths from heart diseases in 1940. The figures cited represent the deaths tabulated as the primary cause in accordance with the rules prescribed in the Manual of Joint Causes of Death. In addition to these figures there were 2,269 cases in which aneurysm of the aorta was involved as a secondary or contributory cause of death. Heart disease was reported as a secondary cause in 112,505 cases. By summing the primary and secondary causes it is found that there were 5,904 deaths in 1940 in

A high mortality of the heart was reported as a primary or secondary cause. Since the weight given to aneurysm of the heart in the joint cause selection is relatively great it may be concluded that cases involving aneurysm of the heart amount to slightly more than 1 per cent of the deaths certified as being due to heart disease. Such an attempt to dupe the unsuspecting public in relation to the selling of insurance should have prompt attention from both the state and federal agencies charged with protection of the public.

THE GENEVA RED CROSS MOVEMENT

The Geneva Red Cross movement is only about 80 years old. From the great and unnecessary human suffering and loss of life during the Crimean War and on the bloody field of Solferino came the impetus for the organization of the Sanitary Commission in the United States in 1861 and for the Geneva Convention in 1863. The two movements, which developed independently in the United States and in Europe, united in one great humanitarian activity at the international congress at Geneva in 1864. The ten articles agreed to at that congress between plenipotentiaries of twelve countries received the eventual adherence of forty additional ones, including the United States. In essence these articles provided for the neutrality of the personnel of the medical services of armed forces (this did not exist throughout most of the American Civil War), the humane treatment of the wounded, the neutrality of civilians who voluntarily assisted the wounded and an international emblem to mark medical personnel and materiel. The ten articles were later expanded by congresses at Geneva in 1906 and 1929 and have been ratified by practically all civilized governments. The development of this movement has just been reviewed and annotated by Love.¹ The publication includes a list of nations which ratified the various treaties—not only those mentioned but also the Hague conferences of 1899, 1904 and 1907. The Geneva Prisoners of War Convention signed at Geneva on July 27, 1929, was never ratified by Japan although it was agreed to by both Germany and Italy. However, on Dec. 18, 1941 the Department of State requested the Swiss government through its representative at Tokyo to transmit to the Japanese government the information that the United States government expected to adhere to the Geneva Prisoners of War Convention and the Geneva Red Cross Convention, both of July 27, 1929, and that the government of the United States hoped that the Japanese government would apply the provisions of the two conventions reciprocally. On Feb. 4, 1942 a telegram was received from the American legation at Berne to the effect that the Japanese government had informed the Swiss minister at Tokyo that, "first, Japan is strictly observing Geneva Red Cross Convention as a signatory state. Second. Although not bound by the convention relative treatment prisoners of war, Japan will apply mutatis mutandis provisions of that convention to American prisoners of war in its power."

CHIROPRACTORS' EDUCATIONAL LOAN FUND

A circular is apparently being sent by the National Chiropractic Student Loan Fund, a Committee of the National Chiropractic Association, Inc., to all "Doctors of Chiropractic" and designated a "Personal Message." Two hundred gummed seals of the general style used by the tuberculosis associations, heart associations, the Wild Life Federation and other agencies for raising funds are included with it. The letter exhorts chiropractors to sell these seals to their patients "who should be loyal to our profession and help our struggling students and colleges which are unendowed and unaided by any form of taxation." The letter further says that "some doctors [sic] give patients seals for use on their mail." The educational institutions for which support is thus solicited are described in an article by one "Doctor" John J. Nugent, National Chiropractic Association Director of Education, who thus reveals the low grade of chiropractic education.¹

Our schools present a museum of diversity—a conglomeration of ideas, practices and prejudices as diversified as the individuals who controlled their destinies.

Disregarding the complete lack of scientific evidence to support the basic tenet of chiropractic, Nugent admits the cursory character of chiropractic education.

The only valid criticism which has been leveled at us has been the continued existence of the short course schools. A tolerant public has in the past borne patiently with us as we explained the necessary evolution of a pioneer science but public opinion does not remain static. We cannot impose too long or too frequently on good will. We have outworn our threadbare arguments in trying to explain away this defect in our education. The public is now accepting them with a grain of salt."

What is to be gained by spending more hours of study on a system of healing that has never been scientifically established? Chiropractors themselves seem to fear that education will expose the utter absurdity of the theory on which chiropractic is based. Thus Nugent says:

Parenthetically I might say that if the statement is made anywhere that this effort to elevate educational standard has for its ulterior motive the destruction of Chiropractic that statement is false without foundation or logic.

More time spent on anatomy, physiology and pathology would soon make any intelligent student unwilling to give serious consideration to the ridiculous fallacies of the chiropractic concept. The idea of securing contributions from the patients or rather the victims of chiropractic to promote perpetuation of this pseudo science is a sort of cynical effrontery typical of the methods by which these peculiar practitioners have reached their present position on the American medical scene. Significantly, this is still the only country in the world that gives any kind of legal recognition to the "chiro."

¹ Excerpt from the National Chiropractic Journal, October 1941 (official organ of the National Chiropractic Association). "Educational Standards. A Frank Discussion by NCA Director of Education Dr. John J. Nugent, New Haven, Conn."

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

THE ARMY'S HEALTH

The United States Army in training in this country is in better health than ever before during wartime, the War Department announced on September 17. On the basis of figures to date it is anticipated that the general hospital admission rate will be about 10 per cent lower in 1942 than in 1941. Thus far in 1942 there has been no mild influenza epidemic like that of early last year. Even the common ills such as colds, sore throat and measles are down to as low a level as reasonably can be expected. Venereal disease is substantially less than during the first world war, with the syphilis rate now lowest in army history. The total venereal disease rate, on an annual basis, was 40.5 per thousand men in 1941 and 38 per thousand men for the first six months of 1942, including cases arising in newly inducted soldiers in whom the infection actually was acquired in civil life. This means that about nineteen new infections occurred among every thousand men during the first half of this year. Soldiers thus infected lose an average of eighteen days or less from duty.

Throughout 1941 and thus far in 1942 the death rate has been the lowest in army history. During this period from one half to two thirds of the deaths resulted from external causes such as traffic accidents. Overseas forces and battle casualties are excluded. About 1 meningitis case in 3 was fatal during the first world war, but this death rate is now down to 1 in 20. Promptness of diagnosis and use of newer treatment are principal reasons. The meningitis fatality rate in the Army is far below that in civil life. The malaria rate per thousand men annually in the continental United States is only 0.61 for the first eight months of 1942, by contrast with 1.24 in the 1941 comparative and the autumn rise in incidence is expected to be less than a year ago. Universal vaccination has virtually eliminated smallpox. Rigid sanitary control and vaccination has made typhoid almost nonexistent in the Army. The incidence of scarlet fever is now extremely low. While the health of the Army in training at home is better than in 1941, nevertheless last year's army health record was unusually good. This experience is the more remarkable, considering the Army's rapid expansion.

THE HEROIC RUSSIAN ARMY DOCTORS

According to the information bulletin of the Soviet embassy in Washington, as stated in the New York Times, the Russian surgeon Prof. Alexander Vishnevski has performed hundreds of difficult operations in field hospitals in the present war. During an operation the patient while on the table was struck by a machine gun bullet from an enemy airplane. Vishnevski immediately extracted the bullet from the patient's limb and proceeded to the next case. Once he is said to have drawn blood from his own veins with which he gave a transfusion to a small child injured when an air raid shelter was blown up by the enemy.

When German bombings destroyed a hospital in Sevastopol during the siege a military physician of the naval air force, Elena Narbut, transferred all wounded patients to an underground vault which had been evacuated during the siege of 1854. A Tass correspondent visited one of these hospital wards. He said that the operating room underground was located where man has not set foot for nearly ninety years and yet it was lighted with electricity, the walls were painted, the floor was covered with linoleum and there was plumbing. The correspondent attended an operation performed in this room by a naval surgeon on a badly wounded Russian soldier who an hour after the operation was evacuated with other serious cases from Sevastopol by ambulance plane.

INDUSTRIAL SAFETY AND HYGIENE CONFERENCE

The War Department announces that the health and safety of war workers in army ordnance plants will be the subject of an industrial safety and hygiene conference held in the Big Four Building in Cincinnati on September 17 and 18. The conference will be attended by more than one hundred medical directors and safety engineers from about sixty ordnance department arsenals and manufacturing plants. Fifteen specialists on industrial safety and health will address the conference on employment hazards and occupational diseases. Col. A. B. Johnson, chief of the plant security branch of the ordnance department, who will preside, said that the recent employment of women, older workers and handicapped persons has increased the necessity for maintenance of health and safety in ordnance plants and that our vigilance over the health and safety of workers must be keener than ever.

DOMESTIC SUPPLY OF CREAM OF TARTAR

The Office of War Information has announced that the Beverage and Tobacco Branch of the War Production Board is assisting the wine industry in the production of cream of tartar to replace supplies which have been shut off by the war. "Cream of tartar," the common name for potassium bitartrate, is a by-product of wine production and can be obtained from grape pomace, residue from wine tanks and dealcoholized residues from brandy distillation. Potassium bitartrate is used in the production of explosives, medicines, rayons, dyes, beverages, photographic materials, baking powder, tobacco and paper. The United States formerly depended on imports from France, Italy and Spain and more recently from South America. It is necessary now for the United States to develop a domestic supply of "tartrate."

The Beverage and Tobacco Branch of the War Production Board is sending a consultant to the wine producing areas to assist in producing "tartrate" without the use of critical materials. The United States wine industry has the capacity to produce about 10,000,000 pounds of "tartrate" a year, which, with the present stock pile, should be sufficient to meet future requirements. In 1941 the consumption of tartrate in the United States was 14,700,000 pounds. In 1942 the United States industry will produce about 5,000,000 pounds of tartrate, and by the end of 1943 production will be increased to capacity.

SHEEP INTESTINES FOR SURGICAL SUTURES

The War Production Board has instructed large meat packers to make no deliveries of sheep intestines until all purchase orders for the purpose of manufacturing surgical sutures are filled. Those who desire to purchase sheep intestines for surgical gut are now required to make a certification to that effect to the packer. Packers covered by the order are those who slaughtered more than 100,000 sheep in the year prior to September 8.

Stocks of finished surgical sutures are low. Under the present practice only the first 9 yards of sheep intestines is used for surgical gut. The remainder, normally 15 to 18 yards, is used principally for sausage casings, tennis racket strings and music strings.

The new order (M 220) makes available the entire sheep intestine for the manufacture of sutures. Hog intestines can be used for sausage casings and tennis racket strings, and parts of sheep's intestine not suitable for sutures will be available for music strings.

It was not found practical to include in the new order small meat packers or those west of the Rockies because of transportation problems.

ARMY DOUBLES OFFICER CANDIDATES IN MEDICAL ADMINISTRATION SCHOOL

In its program to relieve Medical, Dental and Veterinary Corps officers from administrative work for professional duties the War Department has announced that it will double the capacity of the Medical Administrative Corps Officers Candidate School at Camp Barksley, Texas. As a result the class of officer candidates enrolled for the training course on September 26 will be twice the size of previous classes. Medical Administrative Corps officer candidates are chosen from among applicants of the enlisted ranks of the Medical Department or other branches of the Army who have demonstrated qualities of leadership during their basic training.

The officer candidates are trained in the duties of maintaining hospital records, supply accounts, mess management and other administrative tasks to serve as adjutants, inspectors, mess officers and other positions. On successful completion of the course, candidates are commissioned as second lieutenants in the Army of the United States. A Medical Administrative Corps Officer Candidate School is also operated at Carlisle Barracks, Carlisle, Pa.

CONSERVATION OF AGAR

Among the substances now needed in bacteriologic studies related to the war is agar. Agar is the basis for bacteriologic mediums. The War Production Board has already issued an order related to the conservation of this substance. Some physicians have endeavored to secure the release of certain amounts of agar for the treatment of chronic constipation. As every physician knows innumerable substances are available for the treatment of constipation. Moreover, there are now available in commerce many substances which may be substituted for agar which are not particularly needed in bacteriologic study, including, for example, psyllium seed. The small amounts of agar used in preparation of emulsions are not particularly involved, but only the preparations of quarter pound, half pound and 1 pound packages of this substance. It is believed that restriction on the use of agar at this time will not be harmful to the health of any one and that physicians will gladly cooperate in restricting their prescriptions for chronic constipation at this time to other substances.

AVIATION MEDICAL EXAMINERS

A course of instruction to qualify medical officers for duty as aviation medical examiners began at the School of Aviation Medicine in Texas, August 10. The following officers were enrolled:

ARKANSAS		CONNECTICUT	
Jack R. Ellis 1st Lieut.	Hot Springs National Park	Harold W. Duenebauer 1st Lieut.	Hartford
David D. Fried 1st Lieut.	Big Fork	Gershon B. Silver Capt.	Hartford
Elmer J. Ritchie Capt.	North Little Rock	William E. Swift Jr. 1st Lieut.	Hartford
Jett O. Scott Capt.	Hot Springs National Park		
George B. Talbot, Capt.	Pine Bluff		
CALIFORNIA		DISTRICT OF COLUMBIA	
Thomas A. Collins 1st Lieut.	Fresno	George J. Fleury Jr. 1st Lieut.	Washington
Albert E. Fleming 1st Lieut.	Fresno	Harold A. Timreck 1st Lieut.	Washington
Thomas M. Fullenlove Capt.	San Francisco	Fred J. Wertz 1st Lieut.	Washington
Herbert W. Jenkins 1st Lieut.	Palo Alto		
Nicholas G. Maximov Capt.	San Francisco		
Frederick J. Northway, 1st Lieut.	San Francisco		
George M. Plagens 1st Lieut.	San Diego

ORGANIZATION SECTION

MEDICAL LEGISLATION

DISABILITY INSURANCE AND HOSPITAL BENEFITS

PREPARED BY THE BUREAU OF LEGAL MEDICINE
AND LEGISLATION, AMERICAN MEDICAL
ASSOCIATION

In his budget message submitted to the Congress Jan 7 1942, President Roosevelt said in part

I recommend an increase in the coverage of old age and survivors' insurance addition of permanent and temporary disability payments and hospitalization payments beyond the present benefit programs, and liberalization and expansion of unemployment compensation in a uniform national system I suggest that collection of additional contributions be started as soon as possible, to be followed one year later by the operation of the new benefit plans'

An editorial comment on the President's recommendation especially authorized and approved by the Board of Trustees was published in THE JOURNAL, March 7 That statement concluded

'The American people are not averse to immense sacrifice—even to the ultimate sacrifice—if it will win the war They should not be compelled in the midst of such sacrifice, to consider radical proposals for changing the whole system of American living in health or in illness The proposed expansions of the Social Security Act related to medical care should be considered in times when they can be given that type of deliberate meticulous consideration which carefully weighs every aspect of the problem concerned'

On September 9, Representative Eliot of Massachusetts introduced H R 7534, a bill to amend and extend the provisions of the Social Security Act This bill attempts to translate into legislation the recommendation made by the President on January 7 Here is an analysis of those provisions of the bill that seem to be of particular interest to the medical profession

AN ANALYSIS OF H R 7534

In General—This bill, to be cited as the Social Security Act Amendments of 1942, proposes to amend and extend the provisions of the Social Security Act by establishing a Federal Social Insurance System This system will be financed from a Federal Social Insurance Trust Fund consisting of the securities held by the Secretary of the Treasury for Federal Old Age and Survivors Insurance Trust Fund (already established under existing law) together with funds to be made available by means of the contributions provided for in the bill This trust fund will be managed by a board of trustees composed of the Secretary of the Treasury, the Secretary of Labor and the chairman of the Social Security Board, all ex officio Separate accounts within the trust fund may be established as the board of trustees deems necessary or desirable

Contributions to the Trust Fund—Employers coming within the provisions of the bill, except as noted later, will be required to make "social insurance contributions" equal to the following percentages of wages paid by them after Dec 31, 1942 with respect to wages paid during the calendar years 1943 1944 and 1945 the rate will be 5 per cent, for 1946, 1947 and 1948 the rate will be 5.5 per cent and thereafter the rate will be 6 per

cent Employees will be required to make contributions equal to the same percentages of wages received The term "wages" does not include that part of the remuneration which, after remuneration equal to \$3,000 has been paid to an individual with respect to employment during any calendar year after Dec 31 1942 is paid to such individual with respect to employment during such calendar year The bill also excludes from the meaning of the term "wages" certain other payments made by employers

Every self-employed individual will make a social insurance contribution equal to the following percentages of the market value of his services rendered as a self-employed individual, after Dec 31 1942 with respect to services in self employment after such date not including that part of any remuneration for employment and the market value of services in self employment in excess of \$3,000 for any calendar year for the calendar years 1943 1944 and 1945 the rate will be 4 per cent, for the calendar years 1946 1947 and 1948 the rate will be 5 per cent and thereafter the rate will be 6 per cent

Services performed in the employ of a corporation, community chest fund or foundation organized and operated exclusively for religious charitable scientific, literary or educational purposes now exempt from the operation of Social Security Act will be brought within the provisions of the act by the pending bill Employers in such employments will be required to make social insurance contributions as follows with respect to wages paid during the calendar years 1943 1944 and 1945 the rate will be 2 per cent for 1946, 1947 and 1948 the rate will be 2.5 per cent and thereafter the rate will be 3 per cent Employees in such employments will be required to make contributions at a similar percentage of wages received

Federal Old Age Survivors and Disability Insurance Benefits—Existing provisions of the Social Security Act providing for federal old age and survivors benefits are amended in numerous respects and in addition there is added a provision under which disability benefits will be paid The term 'disability' is defined to mean total and permanent disability to work by reason of illness or injury An individual is to be considered totally and permanently unable to work when he is afflicted with any impairment which continually renders it impossible for him to engage in any substantially gainful work and which is founded on conditions which render it reasonably certain that it will continue to be impossible to do so throughout the remainder of his life No individual is to be deemed under disability for any period prior to the sixth month before the month in which he filed application for disability benefits

In addition to cash disability benefits, the bill will authorize the Social Security Board to "make provisions for furnishing of medical, surgical institutional rehabilitation or other services to individuals entitled to the cash disability benefits if such services may aid in enabling the individuals to return to gainful work Such services the bill provides, shall be furnished by "qualified practitioners" and through governmental and nongovernmental hospitals and other institutions qualified to furnish such services The construction of hospitals or other institutions is not authorized Expenditures for these services may not, during the period Jan 1, 1944 to June 30 1945 exceed \$400,000 Thereafter, expenditures may not exceed 2 per cent of the total amount expended during the preceding fiscal year for the payment of disability benefits

This portion of the bill also brings within the Federal Old Age, Survivors and Disability Insurance Benefits provisions self-employed individuals and certain employments not included under the existing law, such as services performed in the employ of corporations and associations organized for scientific, charitable and educational purposes.

Federal Unemployment Insurance and Temporary Disability benefits—This section proposes to federalize unemployment insurance and temporary disability benefits. Grants that are being made at the present time to states for unemployment compensation will cease after the fiscal year ending June 30, 1944, and the program proposed by this section will become effective. Unemployment benefits, under a schedule set out in the bill, will be paid to the individual by the federal government out of the Federal Social Insurance Trust Fund.

Cash benefits are proposed also when an individual by reason of illness or injury is temporarily totally unable to work at his "last, accustomed or reasonably similar occupation," as may be determined by the board. To entitle an individual to disability benefits, he must be "certified as disabled" in accordance with such regulations as the board may prescribe and he must have been continuously disabled for a waiting period of one week immediately prior to any week with respect to which disability is claimed.

In addition to disability benefits otherwise payable, the bill provides a weekly maternity benefit, to be paid in cash, for a period of not more than twelve consecutive weeks, commencing not earlier than six weeks prior to the week in which confinement is expected and terminating not later than six weeks subsequent to confinement. A woman, otherwise eligible for disability benefits, may obtain the maternity benefit if she has during the twenty-six consecutive week period immediately preceding the week in which her confinement is expected to occur complied with such regulations with respect to antepartum care as may be prescribed by the Social Security Board, and if she has during the confinement and during each week subsequent thereto with respect to which she claims the maternity benefits complied with such rules and regulations as may be prescribed.

Each individual claiming or receiving disability benefits or maternity benefits, if requested by the board or its duly authorized representative, must submit to an examination by such physician or expert as the board may designate at such reasonable time and place as the board or its representative may direct, and any failure or refusal, without good cause to submit to such examination or an obstruction thereof will result in a forfeiture of such individual's right to such benefits until such examination has taken place.

To aid in carrying out the provisions of this particular section of the bill, the Social Security Board will be required to establish a Federal Advisory Council or councils composed of men and women representing employers and employees in equal numbers and the public for the purpose of formulating policies and discussing problems related to unemployment, employment and disability and insuring impartiality, neutrality and freedom from political influence in the solution of such problems.

Federal Hospitalization Benefits—The hospitalization benefits proposed by this bill will be available to the employed individual and to the wife and dependent children of such individual, provided the employed individual had during a prescribed preceding period been paid wages for employment equal to not less than a stated amount. The term "hospital benefits" is defined to mean an amount not less than \$3 nor more than \$6, as determined by the Social Security Board after consultation with the National Advisory Hospital Benefits Council to be created by the bill, for each day of hospitalization. In lieu of such compensation the board may make arrangements with accredited hospitals for the payment of the reasonable cost of hospital service. Such benefits are not available with respect to any individual whose period of hospitalization was due to an injury or disability arising out of or in the course of any employment nor, apparently, to self-employed individuals, nor with respect to any day of hospitalization for tuberculosis or for mental or nervous diseases after such diagnosis has been made.

The maximum number of days in any benefit year for which any individual may be entitled to hospitalization benefits will be thirty. If, however, the board of trustees finds that a separate account for federal hospitalization benefits in the Federal Social Insurance Trust Fund is adequate, the board may increase the maximum to not more than sixty days in the following calendar year.

Hospitalization must be in an accredited hospital to entitle an individual to the proposed benefits, and the Social Security Board on or before Jan. 1, 1944 must publish a list of institutions found by it to be accredited hospitals. An accredited hospital is defined to mean "an institution providing, at least bed and board, general nursing care, the use of an operating or of a delivery room, ordinary medications and dressings, laboratory and x-ray services, and other customary hospital care and services, and found by the board to afford professional service, personnel and equipment adequate to promote the health and safety of individuals customarily hospitalized in such institution and to have procedures for the making of such reports and certifications as the board may from time to time require to assure that payment of hospitalization compensation will be made only to individuals entitled thereto." The term accredited hospital does not include institutions found by the board to be chiefly devoted to the care of persons afflicted with nervous or mental diseases, tuberculosis or other chronic illnesses. The board may accredit a hospital "for limited varieties of cases" and, in determining the adequacy of the professional service, personnel and equipment of any institution, may take into account the type and size of community which the institution serves, the availability of other hospital facilities and other relevant matters.

The bill establishes a National Advisory Hospital Benefits Council to be composed of members appointed by the Social Security Board and selected by it from the professions and agencies concerned with the operation of hospitals, and other persons informed on the need for or provision of hospital services. This council is to be authorized "to advise" the board with reference to (1) the formulation of standards for accrediting hospitals, (2) the establishment and maintenance of the list of accredited hospitals, (3) the conduct of studies and surveys of the quality of hospitalization services furnished by hospitals, (4) the establishment of special advisory, technical, local or regional committees or commissions and (5) with reference to such other related matters as in the opinion of the board may aid it in the administration of the hospitalization benefits program.

The Social Security Board will be authorized, through agreements or cooperative working arrangements with appropriate agencies of the United States, or of any state or political subdivisions thereof, and with other appropriate public agencies and private persons, agencies or institutions, to utilize their services and facilities. Any person entitled to a hospitalization benefit may transfer or assign such benefit to an accredited hospital or to any other agency or institution utilized by the Social Security Board.

The Social Security Board will, from time to time, certify to the Secretary of the Treasury the name and address of each individual entitled to hospitalization benefits and the amounts of such payments. Payments may be made directly to the individual entitled to the benefits or to such other individual, agency or institution as the board may prescribe, or, if the board so directs, payments will be transmitted to the board for distribution in such manner as it may prescribe.

Individuals in Military Service—This bill contains provisions under which the rights of individuals in service to old age and survivors insurance benefits will be safeguarded and under which unemployment compensation allowances may be granted on termination of military service under conditions set forth in detail in the measure.

Status of Bill—H. R. 7534 is pending in the House Committee on Ways and Means, of which Representative Doughton of North Carolina is chairman.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Changes in Health Officers—Dr Grundy E McDonald resigned as health officer of Long Beach on August 15 and has been succeeded by his assistant, Dr Frank W Stewart—Dr Roscoe C Main, Santa Barbara, has resigned as health officer of Santa Barbara County after thirteen years of service to become senior physician in the communicable disease section of the Los Angeles County Health Department—Dr Irving D Johnson, Marysville, health officer of the Sutter-Yuba County health unit, has been appointed in charge of the unit in Marin County

CONNECTICUT

Care for Children of Employed Mothers—On August 31 President Roosevelt approved the allocation of \$30,427 to the New Haven Board of Education for a program of care for children of war employed mothers. This is the first of many such projects to be financed throughout the country by Latham Act funds, which were made available early this year. The New Haven project will include a war nursery for forty five preschool children and twenty kindergarten children. Plans were developed by the State Teacher's College, which will furnish supervision for the program, the day care committee of the New Haven council, social agencies and the New Haven Public School System. The program meets the standards of care established by the child care committee of the state's defense council and will receive assistance from that group. The nursery will operate five days a week from 6:30 a m to 6:30 p m. Hours will be lengthened, however, and more days included as the need becomes acute.

Course on Industrial Medicine for Physicians—Yale University School of Medicine New Haven, will conduct lectures and seminars on industrial health and medicine in wartime, October 7 to December 23, under the joint direction of Dr William T Salter, professor of pharmacology, Dr John R Paul, professor of preventive medicine, and Charles Edward A Winslow, Dr P H, chairman of the department of public health. The following lectures will be presented:

- Dr Wolfgang F Von Oettingen Bethesda Md Toxicity and Potential Dangers of Aliphatic and Aromatic Hydrocarbons
- Dr Leroy U Gardner, Saranac Lake N Y Dusts and Silicosis
- Dr Robert A Kehoe Cincinnati Toxicity and Potential Dangers of Metals
- Dr Alice Hamilton Hadlyme Toxicity and Potential Dangers of Chlorinated Hydrocarbons
- Dr Louis Schwartz Washington D C Occupational Dermatoses in War Industries
- Lieut Col Anthony J Lanza M C, U S Army Arlington Va, Factory Epidemiology
- Dr Robert S Goodhart Forest Hills N Y Nutritional Problems in Industry
- Lieut Col D B Dill Air Corps U S Army The Influence of Physical Factors upon Fatigue of the Industrial Worker
- Dr Winslow Extramural Factors in Industrial Health
- J J Bloomfield Washington D C New Wartime Problems in Industry
- Dr Lydia G Giberson New York Mental Hygiene in Industry
- Dr Arthur B Landry Hartford Opportunities and Responsibilities of the Medical Profession in Industry

Each lecture will be followed by a seminar. The departments of pharmacology, preventive medicine and public health are cooperating in the program.

DELAWARE

Positions Open in State Health Board—The Merit System Council announces that October 10 will be the closing date for applications to fill the following positions in the state board of health: deputy state (county) health officer \$3,600-\$4,200, director of public health education, \$1,800-\$2,400, junior sanitarian, \$1,200-\$1,680, laboratory technician, \$1,200-\$1,800, director of public health nursing, \$2,700-\$3,300, public health nursing supervisor and consultant nurse in special fields, \$1,800-\$2,250, public health nurse, \$1,500-\$1,920, junior public health nurse, \$1,260-\$1,500, dental hygienist, \$1,080-\$1,320, and nutritionist, \$2,100-\$2,700. All communications concerning these examinations should be addressed to Charles W Bush, Merit System Supervisor, P O Box 1911, Wilmington.

DISTRICT OF COLUMBIA

New District Hospital—The President has approved the construction of a \$3,207,500 hospital for the District of Columbia and the metropolitan area. The plan to provide 550 beds and other facilities is based on recommendations made by the U S Public Health Service and the vital area board of the district, composed of representatives of the city, military services and other federal agencies.

ILLINOIS

Conference on Health of Industrial Workers—A conference on the health of industrial workers was held in Peoria, September 16, the first of a series to be held throughout the state under the auspices of state and local agencies. At a dinner meeting Dr Clarence C Maher, Chicago, spoke on "Are You Fit for Tomorrow? Is Your Heart Next?" and Franklin C Bing, Ph.D., secretary, Council on Foods and Nutrition, American Medical Association, "Can Workers Eat Their Way to Health or Sickness?"

Survey of Handicapped Youths—The women's executive committee of the Illinois Office of Public Instruction will undertake a survey to report on the job abilities of more than 50,000 handicapped youths in Illinois. The objectives will be to place handicapped youths in war jobs, to release present workers for more demanding production or for service in the armed forces and to pave the way to making possible normal working habits for returning soldiers who will be permanently handicapped. When the survey is completed a group of business men will take action to assure the immediate placement of handicapped youths. J Roy Byerley, Springfield, assistant superintendent of public instruction in charge of education of Illinois' handicapped children, will direct the survey, which it is hoped will be completed in late October or early November.

Chicago

Wesley Hospital to Be a Venereal Disease Clinic—The old Wesley Memorial Hospital will be used to house a venereal disease clinic, operated by the city with the aid of government funds. The allocation from the federal government offered by the Federal Works Agency will be for the equipment of the hospital and for its maintenance and operation for one year.

Typhoid Carriers at State Hospital—A two week quarantine was imposed on the Chicago State Hospital at Dunning because of the discovery of 2 typhoid carriers, newspapers reported on August 18. The carriers were to be transferred to the Manteno State Hospital, Manteno, and include 1 new patient and 1 who had been there about nine months. The discovery of the carriers followed an investigation of an outbreak of intestinal disturbances among the patients.

Personal—Dr Max Thorek was recently presented with the Distinguished Citizen Medal by the Veterans of Foreign Wars for his contributions to the welfare of veterans of foreign wars—Dr Noble Sprunt Heaney has been elected president of the medical staff of the Presbyterian Hospital to succeed Dr Wilber H Post, who had held the office since 1939. Dr Arthur E Parmelee and Dr William G Hibbs were reelected vice president and treasurer, respectively. Dr Heaney has been a member of the staff of the Presbyterian Hospital since 1909 and chief obstetrician and attending gynecologist since 1920. He was for many years head of the department of gynecology and obstetrics at Rush Medical College, is now professor of obstetrics and gynecology at the University of Illinois College of Medicine, and formerly was president of the American Gynecological Society.

INDIANA

School for Physical Therapy Technicians—Dr Edwin N Kime professor and chairman of the department of anatomy, Indiana University School of Medicine, Indianapolis, has been named to organize and head a school for physical therapy technicians at the medical school to help meet the demands of such specialists by the armed forces. The course will last six months for a total of 1,000 hours including 200 hours of clinical practice following 800 hours of theory and laboratory work. Students eligible for admission include graduates of approved schools of nursing, graduates in physical education and persons who have received two years of college work which included general physics, general biology and general chemistry. Graduates of the course will be eligible for the U S Civil Service rating of apprentice physical therapy aid and therefore become eligible for service in the armed forces. After six months of satisfactory experience the student may be promoted to the rank of physical therapy aid by the U S Civil Service Commission.

and may be registered by the American Registry of Physical Therapy Technicians. Only registration and graduation fees will be charged.

IOWA

Compulsory Vaccination Rejected by School Board—The Davenport Board of Education concurred at its meeting, August 10, on the recommendation of the city board of health that all children entering school this fall be vaccinated for smallpox and immunized against diphtheria but refused to make the recommendation compulsory. The board took the position that the health board had authority to make vaccination and immunization compulsory, if it wished, but decided that concerning was as far as it would go.

MASSACHUSETTS

District Society Opens Blood Bank—The Worcester District Community Center for aiding transfusions has been incorporated and will be set up in the Bowler residence, recently acquired by the Worcester District Medical Society. The residence is now being converted into a modern civic center to house the blood bank and facilities for the Worcester Medical Library and the *Worcester Medical News* of the district society. Headquarters for the library and *Medical News*, however, will remain at 34 Elm Street until further notice. It is hoped that the new blood center will be available for occupancy by October 1.

MINNESOTA

Radio to Be Used in Mental Hygiene Program—The Minnesota Mental Hygiene Society has announced a broadened educational program which will utilize the radio as the primary medium. The society believes that there is an expanding need for mental hygiene on a wide scale, and present plans contemplate the presentation of talks by all available psychiatrists in Minneapolis, St. Paul and the adjoining territory.

Murray County Accredited for Human Tuberculosis Control—Murray County is the third county to be selected for accreditation of control of human tuberculosis, newspapers reported on August 23. The presentation of a certificate by the state medical association and the state department of health took place during special ceremonies at Slayton, August 28. Lincoln and Olmsted counties received the first awards and Stevens County was announced as a tentative fourth selection.

Health Center Turned Over to Sister Kenny—The Minneapolis *Journal* reported on August 13 that the Public Health Center was to be turned over to Sister Kenny to establish a treatment center for poliomyelitis. This decision was reached at a meeting of the board of public welfare on August 12 and was a gesture of appreciation to Sister Kenny for establishing Minneapolis as her headquarters while in this country. Newspapers report that the Kenny clinic would be set up in the Public Health Center as soon as arrangements had been completed to move clinics that now occupy the building.

Northern Minnesota Meeting—The Northern Minnesota Medical Association held its annual session at the Brehm Hotel in Bemidji, August 29. The speakers were Drs. Curtis B. Nessa, Minneapolis, on "X-Ray Diagnosis of Abdominal Disease", Walter S. Neff, Virginia, "Shock Associated with Burns", Ralph K. Ghormley, Rochester, "Lumbosacral Pain", Herbert Z. Giffin, Rochester, "Miscellaneous Observations on the Diagnosis and Treatment of Anemia", Frederic T. Becker, Duluth, "Acute Dermatological Conditions," and Edward L. Tuohy, Duluth, who conducted a pathologic conference. Governor Stassen was the principal speaker.

MISSISSIPPI

Changes in Health Officers—Dr. Frank L. McGahey, formerly of Calhoun City, has been appointed chief of the Grenada County Health Department. Dr. Curtis M. Roberts, New Albany, has resigned as health officer in Prentiss County to accept a similar position in Clay County. Dr. George E. Riley has been appointed director of Hinds County Health Department, Jackson.

Professor of Pharmacology Goes to South Carolina—Robert P. Walton, Ph.D., professor and head of the department of pharmacology, University of Mississippi School of Medicine, University, has accepted a professorship in pharmacology at the Medical College of the State of South Carolina, Charleston. Dr. Walton, who has been at Mississippi since 1937, received his Ph.D. at Columbia University, New York.

Society News—The Northeast Mississippi Thirteen County Medical Society was addressed in Amory, September 8, by Drs. Benjamin C. Tubb, Smithville, on "Cardiac Conditions Frequently Met in General Practice", Elham B. Burns and

John A. Ryburn, Pontotoc, "Simultaneous Extrauterine and Intrauterine Pregnancy", John Shelton Horsley, Richmond, Va., "Some Aspects of Cancer of the Stomach," and William H. Anderson, Booneville, "Some Essentials in Lowering the Death Rate in Appendicitis."

MISSOURI

Annual Fall Conference—The Kansas City Southwest Clinical Society will hold its annual fall conference at the Little Theatre, Kansas City, October 5-8, under the presidency of Dr. Jess V. Bell, Kansas City. Included among the speakers will be

Dr. Cornelius P. Rhoads, New York, Nutrition and Cancer
Dr. Byrl R. Kirklin, Rochester, Minn., Cancer of the Gastrointestinal Tract, Its Early Manifestations
Dr. Robert L. Sanders, Memphis, Tenn., The Gallbladder and Duct Problem
Dr. Roy B. Henline, New York, Diagnosis and Treatment of Early Carcinoma of the Prostate
Dr. S. Marx White, Minneapolis, Management and Training for the Patient with Essential Hypertension
Dr. Norman C. Wetzel, Cleveland, Assessment of Physical Condition in Children by the Grid Technique
Dr. Thomas L. Carmody, Denver, Sinus Disease in Children
Dr. Philip D. Wilson, New York, Sciatica and Back Pain
Dr. Noble Sprout Heaney, Chicago, Pains in the Pelvis and Their Significance
Dr. Richard H. Freyberg, Ann Arbor, Mich., General Management of the Patient with Rheumatoid Arthritis
Dr. Wesley W. Spink, Minneapolis, Chemotherapy of Infectious Diseases
Dr. Colby Pitcher, Nashville, Tenn., Diagnosis and Treatment of Cranio cerebral Injuries
Dr. Geza de Takats, Chicago, Pulmonary Embolism
Dr. Walter A. Fansler, Minneapolis, Carcinoma of the Rectum: Outline of Diagnosis and Treatment
Robert Graham, D.V.M., Urbana, Ill., Relation of Animal Diseases to Public Health

At a joint meeting of the clinical society with the Jackson and Wyandotte county medical societies Monday evening, Dr. Wilson will speak on "Management of Compound Fractures Resulting from Enemy Action." Col. Fred W. Rankin, Lexington, Ky., President of the American Medical Association, will also address this session. Discussions at the round table luncheons each day will be on some phase of civilian defense, chemical warfare or war medicine. A wide range of subjects will be covered in the refresher courses which will be held throughout the conference.

NEW YORK

Academy of Medicine Opens Fall Program—The Rochester Academy of Medicine will open its fall program October 6, with a talk by Dr. Oswald H. Robertson, professor of medicine, University of Chicago School of Medicine, on "Air Borne Infections." Dr. Roy G. Hoskins, Boston, will speak November 3 on "Endocrinology of Today" and in December Dr. Fred W. Stewart, New York, will discuss "The Effect of Diet and Diet Deficiencies on the Production of Cancer."

Campaign Against Home and Farm Accidents—A plan of public education to prevent "off the job" accidents has been set up by the New York State War Council through its Office of War Information Service, in cooperation with the division of public health education of the state department of health. Educational material will be disseminated by representatives of the public information service and local war councils as well as by radio commentators and columnists. State and local agencies are cooperating in the project, which will attempt to deal more with principles rather than to point out in great detail accident hazards. The state plan is a part of the national campaign conducted under the auspices of the National Safety Council.

Mental Hygiene Unit—The mental hygiene unit in the Suffolk County Department of Health has completed its first year. According to *Public Health Reports*, of the first 200 cases one fourth were examined for the Juvenile Court and Probation Department, another fourth were referred by the county social agencies, and the other half were studied for the schools and family physicians. Eleven and five-tenths per cent were educational or learning disabilities, 14.5 per cent were found to be mentally deficient. Five per cent had evidences of major physical defect. Thirty-three per cent were behavior and social problems. About 500 school children have been surveyed by group testing methods as a demonstration project, and clinical service has been rendered in 250 cases. Under the setup the health department unit is responsible for all juvenile court cases, while the state hospital clinics care for all school cases in the area of their traveling clinic locations. The program is aimed at prevention, every effort being made to adjust children in their own homes and the community. Of the 29 frankly feeble-minded cases uncovered, only 17 required institutional-

ization for training or protection. Dr. George M. Lott, Amityville, Long Island, is director. The clinical staff is composed of a psychiatrist, a psychologist, two psychiatric social workers and a secretary. According to a report of the director, the unit is believed to be the first mental hygiene service organized under a county health department. The county board of supervisors made an initial appropriation of \$17,000 to establish the service.

New York City

Reconstruction Surgery Ward—The Manhattan General Hospital dedicated a new reconstruction surgery ward on July 30 to the improvement of congenital and acquired disfigurements that impair the normal development of children and lower the morale or the employability of men and women. Dr. I. Daniel Shorell is in charge of the ward.

Dazian Fellowships Awarded—Mount Sinai Hospital announces the award of the Dazian fellowships to Drs. Enrique Washington Lithgow of the Dominican Republic and Dr. Oscar Martinez Gomez, Mexico, serving in the pathology laboratory and gastroenterologic services respectively at Mount Sinai. Awarded to strengthen good will between the United States and Latin American countries, the fellowships covering a year of research at Mount Sinai are supported by the Dazian Foundation for Medical Research. Dr. Lithgow is beginning his second year of work at Mount Sinai on a Dazian fellowship and on its completion will probably return to the Dominican Republic to teach pathology at the medical school of the University of Santo Domingo. Dr. Gomez has been on service at the Civil Hospital at Tampico, Mexico.

Course on Industrial Medicine—The Long Island College of Medicine will conduct a course on industrial medicine for two weeks beginning November 2. Internships in the industrial medical department for the month following the course are being arranged for those who wish additional training. The course is intended primarily for qualified physicians who are either now engaged in industrial practice or who desire to enter the field. A tuition fee of \$75 will be charged for the full two weeks course. The fee is \$60 per person when two or more enroll from the same industrial concern. Special arrangements will be made in the case of industrial nurses, executive officers interested in health matters, personnel department representatives or others who may wish to attend a few of the sessions. A complete program may be obtained from the Office of Administration, Long Island College of Medicine, 350 Henry Street, Brooklyn.

Regulations Governing School Health Tests—Beginning with the fall school term all teachers and other school employees in public private and parochial schools must pass a physical examination on appointment and a checkup examination every two years thereafter in accordance with regulations adopted by the city department of health effective October 1. The physical examination will place particular emphasis on tests for tuberculosis and other communicable diseases. Under the new regulations, pupils entering parochial and private elementary schools either will have to have a certificate of health obtained from examination by their own physician or pass such an examination by the school physicians. Health department physicians will do this work where private schools are not able to do it. According to the *New York Times* it also is intended that periodic reexaminations as given by city physicians in public schools two or three times during each child's elementary school career will be done by health department physicians as far as possible. The regulations also cover hygienic standards of minimum floor and air space, toilet and drinking facilities and similar measures.

NORTH CAROLINA

Personal—Dr. Milton B. Clayton, Statesville, has been appointed chief surgeon of the Southern Railway System with headquarters in Washington, D. C. The appointment was effective on September 1.—Dr. Charles H. Phillips, Thomasville, was guest of honor at a dinner given by the Davidson County Medical Society to observe his completion of fifty years in the practice of medicine. He was presented with a gold-headed cane.

NORTH DAKOTA

Director of Maternal and Child Hygiene Appointed—Dr. Robert G. White has been appointed director of maternal and child hygiene for the state department of health, effective September 15. Dr. White has been health officer of District number 4 at Valley City. He has been succeeded there by Dr. Edwin L. Sederlin, formerly health officer of Fargo.

PENNSYLVANIA

Society News—Dr. Robert W. Staley, Pittsburgh, addressed the Clearfield Medical Association, August 20, on "Recent Advances in Psychiatry."—Dr. Eldridge L. Chason Philadelphia, discussed "Surgical Aspects of Acute Intestinal Obstruction" before the Harrisburg Academy of Medicine, September 15.

New Tuberculosis Organizations—The *Bulletin* of the Pennsylvania Tuberculosis Society announces the organization of a new group in Mercer County and one in Northumberland. Carroll D. Keams, superintendent of schools in Farrell, is president of the Mercer County Tuberculosis and Public Health Society and Dr. James A. Biggins, Sharpsville, is the secretary. Miss Ellen Kuhlmann, Oil City, is the executive secretary. Rev. C. F. Berkheimer, Sunbury, is president of the Sunbury-Northumberland Tuberculosis and Health Society and Mrs. Rachel Snyder Bell, R. N. Northumberland, the executive secretary.

Pittsburgh

District Meeting—Training Physicians for Placement in War Industries was the theme of a program presented before the Tenth Councilor District of the Medical Society of the State of Pennsylvania, September 15. Among the speakers were:

- Dr. Alfred I. Chudwick, New Brighton, Pa.: Newer Hazards in War.
- Dr. Joseph Shulen, Pittsburgh: The Role of the State Health Department in War Industries.
- Dr. Walter I. Donaldson: Medical Profession Challenged.
- Dr. Orlen J. Johnson, Chicago: The Profession's Responsibility in War Time Industries.
- Dr. Charles H. Hemminger, Pittsburgh: Civilian—Including Industrial—Needs for Services of Physicians.
- Mr. Ralph E. Pinley, Beaver: Response from Small Industry.

TEXAS

Personal—Dr. Joseph T. Roberts, assistant professor of medicine and anatomy, University of Texas Medical Branch Galveston, has been appointed director of the Experimental Laboratory of the school.—Dr. Henry T. Safford Sr., El Paso, was elected the first honorary member of the Texas State Association of Medical Anesthetists at its recent annual meeting in Houston.

State Cancer Hospital Project Under Way—The M. D. Anderson Foundation, Houston, recently purchased the 6-acre estate of the late Capt. James A. Baker for use as temporary quarters of the Texas State Cancer Hospital and Research Laboratories. The property will be donated to the University of Texas as temporary quarters for the hospital and laboratories until a permanent plant can be built. The last legislature appropriated \$500,000 for the project and the Anderson Foundation agreed to donate a site and to give \$500,000 in addition according to the state medical journal. On August 1 the board of regents of the University of Texas appointed Dr. Ernst W. Bertner, Houston, as temporary director of the hospital and laboratories. He was president of the Texas State Medical Association in 1938.

UTAH

Dr. Callister Named Dean of Utah Medical School—Dr. Alfred Cyril Callister, Salt Lake City, has been appointed dean of the University of Utah School of Medicine, Salt Lake City. Dr. Clay B. Freudenberger, professor of anatomy and formerly acting dean, has been appointed associate dean. Other new appointments include those of Louis P. Gebhardt Jr., Ph.D., as associate professor of bacteriology and pathology and Robert E. Hoyt, Ph.D., as assistant professor of bacteriology and pathology. Dr. Gebhardt was formerly acting assistant professor of bacteriology at Stanford University School of Medicine, San Francisco, and Dr. Hoyt, instructor in bacteriology in the University of Minnesota Medical School, Minneapolis.

VERMONT

State Medical Meeting—The Vermont State Medical Society will hold its annual meeting at the Pavilion Hotel, Montpelier, October 1, under the presidency of Dr. Ernest H. Butties, Burlington, who will discuss "Medical Care in Vermont." The speakers will include:

- Dr. Charles P. Chandler, Montpelier: The Diagnosis and Treatment of Mechanical Intestinal Obstruction.
- Dr. Robert W. Wilkins, Boston: The Use and Abuse of Sedative.
- Dr. Joseph F. Ross, Boston: The Diagnosis and Treatment of Anemia.
- Dr. Howard M. Clute, Boston: The Pathology and Treatment of Acute Cholecystitis.
- Dr. Chester S. Keefer, Boston: Some of the Problems Concerned With the Interpretation of Abdominal Pain.
- Dr. Samuel N. Vose, Boston: Urinary Tract Infections—Their Diagnosis and Management.

VIRGINIA

State Medical Meeting in Roanoke—The Medical Society of Virginia will hold its annual meeting at the Hotel Roanoke in Roanoke, October 5-7 under the presidency of Dr. Rosner W. Miller, Richmond. The program includes as guest speakers, Drs. James F. Paulin, Atlanta, Ga., President Elect of the American Medical Association, Julian M. Ruskin, Durham, N. C., on "Anchovy Dysentery," and Robert I. Bennett, Wm. Springs, Ga., local physicians on the program will include:

Dr. William McK. Bickers, Richmond, "Leukorrhea: Its Cause and Treatment";
Dr. Benjamin M. Kagan, Richmond, "The Clinical Significance of the Serum Proteins";
Dr. Thomas Dewey Davis, Richmond, "Acute Cirrhosis of the Liver";
Dr. Paul D. Camp and Louise J. Calkins, Richmond, "Rheumatic Fever and Rheumatic Heart Disease in Virginia";
Dr. Linwood D. Keyser, Roanoke, "The Clinical Manifestations of Colitis and Its Treatment";
Dr. Martin I. Dreyfuss, Clifton Forge, "Benign and Malignant Lesions of the Uterus";
Dr. David C. Wilson, Charlottesville, "Treatment of the Mental Diseases Related to the Involutional Period";
Dr. Warren T. Vaughan, Richmond, "Jaquer Dermatitis".

The staff of Catwaba Sanatorium and the Society of Chest Physicians of Virginia are collaborating in the following program: Dr. Floyd E. Boys, Charlottesville, on "Effect of Heparization on Post-Radiation Tissue Changes in the Lung, An Experimental Report"; Dr. James B. Nicholls and A. W. Bengston, Catwaba Sanatorium, "Report on Culture Work of Microscopically Negative Sputum for Tubercle Bacilli for a Period of Eight Years," and Dr. Emanuel R. Broome, Catwaba Sanatorium, "Bilateral Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis".

WEST VIRGINIA

Rehabilitation Program—Medical care and minor operations through a program of adult physical rehabilitation have enabled 1,532 persons in West Virginia to return to self support during the past fiscal year, according to a report in the state medical journal. The average cost per case was \$99.42. Since the average relief case costs about \$250 a year, it is apparent that the plan effects a large saving of public funds. It was stated: "The total returned to self support during the past fiscal year under this program was more than twice the number during the previous twelve month period. The increase is attributed both to the improved employment opportunities and to the expansion of the state's adult physical rehabilitation program. Since the work of rehabilitation began, 76 per cent have returned to work. The majority of those rehabilitated suffered from hernia. Many others needed dental work, artificial limbs or glasses."

State Cancer Project—On August 11 the first meeting of a special cancer committee, appointed by Gov. M. M. Neely to consider plans for the establishment and maintenance of a state cancer retreat or institution, was held jointly with members of the legislative interim committee. The session was held in the senate chamber in the state capitol and was devoted primarily to a general discussion of cancer. Senator Byron B. Randolph, president of the state senate, announced that Miss Dorothea Campbell, director of the bureau of public health education of the state health department had been directed by Dr. Clifton F. McClintic, state health commissioner, to make a thorough cancer survey of West Virginia by counties with particular reference to the number of cases in homes and hospitals, number of deaths, number being treated and percentage of cures. A subcommittee of the special cancer committee is now carrying on a study of treatment and hospital care in other states in which cancer hospitals are maintained. Complete figures for 1940 show a total of 1,459 deaths from cancer in West Virginia. The complete figures for 1941 are not yet available.

WISCONSIN

University News—The National Foundation for Infantile Paralysis Inc. has given \$1,500 to Marquette University School of Medicine, Milwaukee, to pursue a study of the relationship of nutrition to the morphology and physiology of the neuromuscular apparatus in skeletal muscle.

Personal—Dr. Maurice A. F. Hardgrove has resigned as secretary of the Medical Society of Milwaukee County to enter military service.—Drs. Louis A. Van Altena and Anthony Voskuil, both of Cedar Grove, were honored at a picnic recently given by patients and friends to mark their many years of service in the community. Dr. Van Altena started practice in Cedar Grove in 1895 and Dr. Voskuil in 1909.

GENERAL

Army and Navy E. Awarded to Bauer & Black—Special ceremonies were held at the Bauer & Black plant in Chicago, September 11, to present to the company the joint Army-Navy Production Award for high achievement in the production of essential war materials. The award is an acknowledgment of the large volume of surgical dressings, sutures and military first aid kits produced by Bauer & Black. Brig. Gen. John M. Willis, commanding general, Camp Grant Medical Replacement Training Center, Rockford, Ill., who presented the joint Army-Navy flag to a committee of three consisting of two employees and Mr. R. A. Whidden, president of Bauer & Black. Comdr. L. J. Stein, senior medical officer of the Navy, Chicago, then presented the honorary award E pins that all employees will wear as a symbol of outstanding contribution to the war effort and to the future of America.

Decline in Tuberculosis Death Rate—The National Tuberculosis Association reported that 44 persons died of tuberculosis per hundred thousand of population in 1941 as compared with 46 in 1940. According to figures submitted to the association by state departments of health, 59,173 persons died of tuberculosis in the United States last year and 105,714 new cases of the disease were reported. Arizona with 171 tuberculosis deaths per hundred thousand, has the highest tuberculosis death rate. Other high rates per hundred thousand reported were District of Columbia 82, Tennessee 79, Maryland 74, Kentucky 67 and New Mexico 65. The lowest death rate was reported from Utah with 62 deaths or a rate of 11. Other states with a rate far below the national average are Wyoming 13, Iowa 15, Nebraska 15, Idaho 16, North Dakota 18, New Hampshire 21 and Kansas 22. New York State reported 6,208 deaths, making its rate 45.5. A total of 15,165 new cases was announced.

International Medical Assembly—The twenty-seventh annual International Medical Assembly of the Inter-State Postgraduate Medical Association of North America will be held at the Palmer House, Chicago, October 26-30 under the presidency of Dr. George R. Minot, Boston. The program will include many clinics and the following addresses, among others:

Dr. Alton Ochsner, New Orleans, "Diagnostic Clinic: Intravenous Clottings and Their Sequelae";
Dr. Paul C. Padgett, Kansas City, Mo., "Improved Methods of Skin Grafting";
Dr. Elmer I. Severynhus, Madison, Wis., "The Male Climacteric";
Dr. Ernest Sachs, St. Louis, "Penetrating Wounds of the Head";
Dr. Harold S. Diehl, Minneapolis, "The Common Cold";
Dr. Louis J. Williams, Jr., Atlanta, Ga., "The Practical Aspects of Malaria";
Dr. Tom D. Spies, Cincinnati, "The Use and Abuse of Vitamins."

Dr. Minot will deliver his presidential address at the annual dinner, and other speakers will include Dr. Frank H. Lahey, Boston, "Problems of Medicine During War," and Col. Fred W. Runkin, Lexington, Ky., President of the American Medical Association, "Professional Problems of the Army Surgeon."

Academy of Ophthalmology and Otolaryngology—The forty-seventh annual meeting of the American Academy of Ophthalmology and Otolaryngology will be held at the Palmer House, Chicago, October 11-14, under the presidency of Dr. Ralph I. Lloyd, Brooklyn. Among the speakers will be:

Dr. Marvin F. Jones, New York, "The Autonomic Nervous System in Health and Disease";
Drs. Louis H. Clerf and Floyd Johnson Putney, Philadelphia, "Cricopharyngeal Spasm";
Dr. Anderson C. Hilding, Duluth, Minn., "The Relation of Ciliary Insufficiency to Death from Asthma and Other Respiratory Diseases";
Dr. Henry B. Perlman, Chicago, "The Effect of Noises and Explosives on the Acoustic Apparatus";
Dr. Edmund B. Spaeth, Philadelphia, "Congenital Ptosis: The Variables Present Which Indicate the Necessity for Varied Surgical Procedures";
Drs. Francis Bruce Frisick, James H. Cooper and Richard C. Armstrong, Ann Arbor, Mich., "Management of Iridocyclitic Secondary Glaucoma";
Drs. Conrad Berens and Hunter H. Romaine, New York, "Postoperative Exotropia With Limitation of Adduction—Results of the Transplantation of Tenon's Capsule."

There will be a symposium on chemotherapy in which Drs. John G. Bellows, ophthalmologist, Chicago, Charles T. Porter, otolaryngologist, Boston, and John A. Kolmer, internist, Philadelphia, will speak.

CANADA

Lewis Gross Memorial Lecture—Dr. Boris P. Babkin, research professor of physiology, McGill University Faculty of Medicine, Montreal, will deliver the fifth annual Lewis Gross Memorial Lecture on October 21 at the Jewish General Hospital, Montreal, under the auspices of the Montreal Clinical Society. His subject will be "Respiration of the Functional Capacity of the Stomach Deprived of Its Main Arterial Blood Supply."

Aug. 14, 1942

Thirty Years of National Health Insurance

National health insurance came into operation in 1912 as part of the scheme of the National Insurance Act, which aimed at protecting the workman not only against the effects of illness but also against the effects of unemployment. The provision of cash and treatment benefit during illness was designed to reduce destitution. The cost was jointly provided by the state, the employers and the workmen. Though the workmen only partly paid for the benefits, they bitterly resented enforced payment in the form of stamps. But the opposition did not last, and national health insurance became a part of our social system and grew.

In a survey of the thirty years' working of the scheme the *Times* pronounces it a success. Originally 12 to 13 million persons were entitled to benefit. In 1922 the number reached 15 million, in 1932 was over 18 million and today is between 20 and 21 million. The financial and administrative machinery has worked without a breakdown. Approved societies administer sickness and disablement benefit. The largest of these were formed by and are affiliated with the great life insurance societies and friendly societies and have a vast commercial and actuarial experience. Insurance committees composed of representatives of insured persons, the medical profession and civil servants act in cooperation with various other committees for advice and consultation and administer the medical and pharmaceutical benefits. Supervision and control are exercised by the Ministry of Health. A government actuary is responsible for the quinquennial valuation of the assets and liabilities of all approved societies.

Criticisms have been made by experts. The medical benefits include only the services of general practitioners, which in view of the rapid advance in medical science is often totally inadequate. Any further medical treatment is "an additional benefit," available only if the approved society has a surplus which it decides to distribute for this purpose and if the insured has not exhausted his claim to additional benefit. In England about \$17,000,000 is spent annually on "additional benefits" and of this sum \$14,000,000 is absorbed by dental and ophthalmic benefit. Thus only a small sum is available for such important services as hospital treatment, surgical operations, convalescent homes, medical and surgical appliances and nursing. Maternity benefit is restricted to a small cash benefit. Hence the sick worker has often to fall back on his own savings or on charity or public assistance. There is no provision, as in many foreign schemes, for benefits to dependents.

The Organization of the Treatment of Cancer

The National Radium Commission has collected much information on radiotherapy, including the organization of radiotherapeutic centers. In the twelve years of its work it has been impressed with the fact that the death rate from cancer continues to rise, although its centers treat a constantly increasing number of patients with slow but persistent improvement in the number who survive several years after treatment. The following remediable factors contribute to this paradox: 1. Late diagnosis due to inadequate facilities for diagnosis, inexperience with cancer and ignorance and fear of the disease which prevent the seeking of advice in the early stage. 2. Scarcity of beds for hospital treatment. 3. Failure to select the best treatment for each case, owing to absence in most hospitals of an organized system for consultation between the various specialists whose skill may be required. 4. Inefficient treatment in inade-

quately equipped centers, due to the natural ambition of every hospital to carry out all kinds of treatment, and want of cooperation between medium size and small hospitals to build up joint centers in those specialties in which the needs are more elaborate than their means allow.

The National Radium Commission therefore makes the following suggestions for organization of cancer treatment on a regional basis, which will largely depend on the postwar hospital service which the government has promised to establish. The executive department of the organization should be in the hands of a special cancer committee. A whole time director should be appointed, though he might be allowed to have private patients within but not outside his own hospital. The functions of the cancer organization would be to put before the public those facts about cancer which should be generally known, to secure diagnosis at the earliest possible stage, to secure prompt treatment and to improve treatment. The area to be served should be so large that not fewer than 1,000 cases are treated in a year. This would require a population of about a million. Such a minimum is necessary in order that each member of the team may see enough cases to become expert, that the available radium and x-ray apparatus may be used to capacity and that each type and site of growth may be large enough for statistical analysis in a few years. The staff must include all necessary specialists—physicians, surgeons, gynecologists, radiotherapists, pathologists, radiodiagnosticians and physicists. The organization must be in or in close association with one or more large general hospitals, where a special department or block should be devoted to the work.

In the arrangements for diagnosis many difficulties have to be overcome. General practitioners must be taught to be "cancer conscious" and to send promptly to the organization all persons requiring investigation. For this purpose it may be desirable to have arrangements for diagnosis at several hospitals, which must be visited regularly by members of the team capable of deciding where the patient should be sent for treatment. Lectures should be arranged to encourage patients to seek advice early.

The treatment should be undertaken only after consultation between members of the team. When settled it will be carried out by one of the specialists. At appropriate intervals or at the end of the treatment the patient should be seen again in consultation. The physicians of the organization will not only play a part in diagnosis and treatment but give help in other ways: in recognition of metastases, the study of general reactions to treatment, the prevention and treatment of complications, the supervision of the health of workers with radium and the x-rays. Surgical treatment should be done only by the surgeons of the team of special experience with the operations needed, after consultation with the radiotherapist. Radiotherapy will always have to be concentrated at one or very few of the hospitals taking part in the organization. The radiotherapist should have at his disposal at least 1 Gm. of radium so that he can in every case use the most suitable containers. He should have at least two high voltage therapy sets so that if one breaks down treatment will not be interrupted. Radio diagnosis is necessary not only for diagnosis but at many stages of treatment and in the follow-up of the patient. There must be an expert radiodiagnostician with modern apparatus.

New Camp for War Blinded British Prisoners in Germany

The condition of blinded prisoners of war in Germany has been greatly improved by the decision of the authorities to allow them all to be accommodated in one camp. As far as is known there are about 28 blinded British prisoners in a lovely part of the country with a good stone house as quarters, with a dining hall and tables to eat at. The various organizations which are helping blinded prisoners are fortunate in the

active interest of Lord Normanhby, himself a wounded though not a blinded prisoner. The German authorities have permitted him and Major Chapel to accompany the blinded men to their new camp. They have also consented to the appointment of a German teacher of the blind and of a British noncommissioned officer as assistant to Lord Normanhby.

As to the British prisoners of war in general, official information has been received that they have all been sent to a new camp at Sigm, about 8 miles northeast of Dresden. Preliminary reports of the conditions there are satisfactory.

BUENOS AIRES

(From Our Regular Correspondent)

Aug 15, 1942

Pan American Neuropsychiatric Congress

The third Pan American Neuropsychiatric Congress will be held on November 1942 in Buenos Aires. Dr. Nerio Rojas will be the president. The following official topics will be discussed: (1) conception of abnormal personality, (2) nonsuppurative acute encephalitis, (3) psychopathologic and medicolegal aspects of hunger, (4) neuropsychiatric aspects of Pan American infections, (5) neuropsychiatric manifestations of professional diseases and (6) presenile psychoses. There will be two speakers for each official topic, namely an Argentinian speaker and a speaker of any of the Pan American countries.

Laws on Prevention of Venereal Diseases

Mr. D. Amleto Donadio, the second chief of police of Buenos Aires, lectured recently before the Sociedad de Medicina Legal y Toxicología of the Asociación Médica Argentina. He said that the laws for prevention of venereal diseases in the country were passed in 1937. When the laws on abolition of prostitution were passed, the adversaries to the law were afraid that the attempts at rape might increase, which is not the case. An active campaign was carried on by the police to control infraction of the laws. Groups of infractions were detected 148 times in the course of 1938, 344 times in 1939, 222 times in 1940 and again 224 times in 1941. The number of attempts at rape reported by the police in two different periods of five years each, before and after establishment of the law, are as follows:

Year 1932	201 attempts	Year 1937	224 attempts
Year 1933	202 attempts	Year 1938	206 attempts
Year 1934	230 attempts	Year 1939	228 attempts
Year 1935	240 attempts	Year 1940	210 attempts
Year 1936	264 attempts	Year 1941	234 attempts

Mr. Donadio emphasized the social advantages of abolition of prostitution. Recognition of the latter stimulates celibacy. The country is now in need of an increase in the number of marriages and in the rate of birth. There are only 4 persons for each square kilometer, whereas in Europe there are 140 or 160 persons for the same surface. The number of marriages in Buenos Aires has increased in the last few years. In 1931 there were 19,791 marriages (0.89 per cent in relation to the whole population of the city). From 1932 to 1941 the number of marriages constantly increased. There were 23,141 marriages in 1941 (0.91 per cent in relation to the whole population of the city). The laws against prostitution will be more effective when the authorities are more strict in the enforcement of certain laws. Laws which are related to abolition of prostitution include giving the necessary attention to sexual education of the public, hospitalizing prostitutes with venereal diseases in certain phases of the diseases in which they can contaminate other persons, punishing patients who are responsible for spreading venereal diseases, regarding contamination as a crime, and suppressing places for prostitution. These laws are in effect, but there is a certain laxity in their enforcement.

Research with Wassermann and Kahn Tests in Argentina

The Wassermann and Kahn reactions were performed with the blood of 500 nonselected mothers who were observed in the Eliseo Canton maternity hospital of the Hospital Ramos Mejia of Buenos Aires. The Kahn reaction gave positive results in the blood of 14.4 per cent of the mothers. The results were positive for the standard test in 10.9 per cent and with the presumptive test in 17.8 per cent. One thousand Kahn tests were performed with blood of retroplacental hematoma. The respective percentages of the Kahn reaction as a whole and by the standard and presumptive techniques were 11.2, 9.1 and 13.4. In the blood of newborn infants from these mothers the respective percentages were 3.8, 3.1 and 4.4.

Drs. Miraventi, Parodi and Barba and Mrs. Bononi of the Instituto Bacteriológico del Departamento Nacional de Higiene of Buenos Aires performed the Wassermann and Kahn tests on 23,000 specimens of blood serum. Positive results were obtained in 8 per cent of the specimens with both reactions and in 3.6 per cent of them with one reaction. The results of the Wassermann and Kahn tests agreed in 96.3 per cent and were conflicting in 3.6 per cent. The results of the Kahn test were positive in 1 per cent of the specimens in which the results of the Wassermann test were negative, whereas those of the latter test were positive in 2.6 per cent of the specimens in which the results of the former test were negative. The results of the presumptive Kahn test were positive in 11.3 per cent of the specimens in which the results of the standard Kahn and of the Wassermann tests were negative. They conclude that the serologic studies carried on by both the Wassermann and Kahn tests give better results than those which are carried on by either test alone. The Instituto Bacteriológico has developed a method by which the sensitivity of the standard Kahn test is increased.

Investigation of Tuberculosis

A contribution toward the solution of the problem of the interrelation between social conditions and the incidence of tuberculosis has been made by the examination of the children in modern Jewish agricultural settlements of northern Palestine (Emek Jezreel). A thorough examination of 1,055 children between the ages of 4 months and 15 years, conducted by Dr. Nassari, director of the Children's Department of the Kupat Holim Hospital in Affuleh, revealed a positive tuberculous reaction in only 4 per cent of all the children, while between the 13 and 15 year olds only 6 per cent showed a positive reaction. These figures compare with the lowest in the available statistical data of tuberculous tendencies of the populations of various countries, even taking into consideration the fact that the percentages are of children from rural settlements only. It was found that the positive reaction occurred mainly among children who had previously resided for a considerable period in towns or who had immigrated to this country at a later age of childhood.

This satisfactory state of affairs is largely due to the medical examination of all adults before their acceptance into Kupat Holim (sick fund), to the medical control exercised over a large part of the immigrants entering this country and to the comparative isolation of the children of the rural settlements from the urban population. With a view to combating the disease at the earliest period of infection, a series of examinations was carried out of the nurses, kindergartners, teachers and others in charge of children. Among nearly 500 who were examined clinically and by x-ray, only 12 persons manifested vestiges of former tuberculosis. Active tuberculosis was not discovered in a single case.

Deaths

Herbert Stanley Birkett, Montreal, Canada, McGill University Faculty of Medicine Montreal, 1886 junior demonstrator of anatomy in 1889-1890 and demonstrator from 1890 to 1896, appointed professor of laryngology and otology in 1895 and since 1931 emeritus professor at his alma mater, where he had been dean from 1914 to 1922, specialist certified by the American Board of Otolaryngology, past president of the American Laryngological Association, of the American Otological Society and of the American Laryngological, Rhinological and Otological Society, member of the American Broncho Esophagological Association for many years secretary and later vice president of the Canadian Medical Association, past president of the Montreal Medico-Chirurgical Society, fellow of the American College of Surgeons and of the Royal Society of Medicine honorary president of the Clinical Congress of Laryngology in London in 1919, in 1935 and 1938 vice president of the Pan American Congress, in 1936 represented the Dominion of Canada at the International Congress of Otolaryngology in Berlin was made an honorary member of the Scottish Otological and Laryngological Society in 1924, during World War I was in command of number 3 Canadian General Hospital (McGill) in 1916 was appointed consultant otolaryngologist to the British armies in the Boulogne area, was made assistant director general of the Canadian Army Medical Services Overseas with the rank of Brigadier General in 1918, was awarded the Colonial Officers' Auxiliary Forces Decoration in 1916 and the Jubilee Medal in 1935, honorary physician and Aide-de-Camp to the Governors General of Canada, Lord Byng of Vimy and Viscount Willingdon from 1921 to 1931 was senior house surgeon 1886-1887, and in 1890 joined the laryngologic staff, of which he was later made chief at the Montreal General Hospital where he was life governor physician to the Montreal Dispensary from 1887 to 1889 and laryngologist from 1890 to 1896 for many years head of the department of otolaryngology and later consultant at the Royal Victoria Hospital, consultant to the Alexandra Hospital the Children's Memorial Hospital and the Montreal Foundling and Baby Hospital, formerly president of the Mackay Institute for the Deaf in 1922 was invited by the University of London to give the Semon lecture, in 1928 was awarded the honor medal of the American Academy of Ophthalmology and Otolaryngology, and his election to honorary membership in the academy was the first one ever extended by the society, in 1921 at the centenary of McGill University was given the honorary degree of doctor of laws, aged 78, died, July 19.

Joseph Charles Baird @ Eau Claire Wis. Hahnemann Medical College and Hospital, Chicago 1907, specialist certified by the American Board of Radiology, Inc., member of the Radiological Society of North America Inc. and fellow of the American College of Radiology, past president of the Eau Claire-Dunn-Pepin Counties Medical Society served as a first lieutenant in the medical corps of the U. S. Army during World War I was an instructor of military roentgenology at Cornell University Medical College, New York and worked overseas with Johns Hopkins' unit and the 127th Field Hospital in France aged 58 on the staff of St. Joseph's Hospital Chippewa Falls director of the roentgen laboratory of the Luther Hospital from 1912 to 1923 and director from 1910 to 1937 and since 1940 of the roentgen laboratory of the Sacred Heart Hospital, where he died, August 3 of coronary thrombosis.

Charles Blount Slade, Greenwood Lake N. Y. Bellevue Hospital Medical College, New York 1896, prosector and demonstrator of anatomy from 1900 through 1902 chief of clinic and instructor in general medicine and physical diagnosis and lecturer on life insurance examination from 1905 to 1914 at the University and Bellevue Hospital Medical College, for several years visiting physician in charge of the general medical clinic of De Milt Dispensary physician to the health department of New York City from 1906 to 1933, established the municipal Sanatorium at Otisville N. Y., in 1906 served the U. S. Army examining prospective aviators in the Eastern district of the United States during World War I, author of 'Physical Examination and Diagnostic Anatomy' and 'Establishment and Conduct of a Tuberculosis Sanitarium' aged 68, died, August 23.

Julius Christian Sosnowski Wadmalaw Island S. C., Medical College of the State of South Carolina Charleston 1904 assistant in medicine and lecturer on dietetics from 1910 to 1912 lecturer on medical jurisprudence from 1910 to 1913 lecturer on dietetics assistant clinical surgery, 1912-1913, and lecturer on minor surgery from 1915 to 1919 at his alma mater,

fellow of the American College of Surgeons, lieutenant commander in the U. S. Navy and Marine Corps during World War I, formerly on the staffs of the Roper Hospital, St. Francis Xavier Infirmary and the Baker Memorial Sanatorium of Charleston and the Long Beach Community Hospital, St. Mary's Long Beach Hospital and the Seaside Memorial Hospital of Long Beach, Calif., aged 65, died, July 15, in the Riverside Infirmary, Charleston, of heart disease.

Harry Parks Ritchie @ St. Paul, University of Minnesota College of Medicine and Surgery, Minneapolis, 1896, clinical emeritus professor of surgery at his alma mater and at the University of Minnesota Graduate School, president of the Ramsey County Medical Society in 1915 member of the American Surgical Association, member and past president of the Western Surgical Association, fellow of the American College of Surgeons, specialist certified by the American Board of Surgery and by the American Board of Plastic Surgery, on the staffs of the University, St. Luke's, Miller and Children's hospitals author of a chapter on the lip and the palate in Lewis's 'Surgery', aged 69, died, September 3, of hypertension with cardiovascular complications.

Ira Jay McCurdy, Frederick, Md., Bellevue Hospital Medical College, New York 1892, member of the Medical and Chirurgical Faculty of Maryland, served as chairman of the city police commission and as a member of the city board of health, at one time city and county health officer, commissioned in 1910 as a lieutenant in the medical corps of the Maryland National Guard and served for several years with the militia, was an examiner for the county draft board during World War I, aged 73, died, August 2, in the Frederick City Hospital of complications following injuries received in a fall.

Frank S. White, Terrell, Texas, Central College of Physicians and Surgeons, Indianapolis, 1884, member of the State Medical Association of Texas, formerly medical director of a sanatorium bearing his name and of the Northwest Texas Insane Asylum at Wichita Falls, at one time physician in charge of the Southwestern Insane Asylum San Antonio, assistant physician on the staff of the Terrell State Hospital and superintendent of the Austin (Texas) State Hospital, aged 83, died July 20, in Dallas of carcinoma of the rectum and liver.

William Ethelbert Silcocks, Green Island, N. Y., Albany (N. Y.) Medical College 1897 member of the Medical Society of the State of New York, formerly president of the village of Green Island and health officer, served as school physician and as Albany County coroner's physician, surgeon for the Delaware and Hudson Railroad on the staff of the Cohoes (N. Y.) Hospital, aged 71, died, July 17, of coronary thrombosis and pulmonary embolism.

Edward Povers Norcross @ Highland Park Ill. Northwestern University Medical School Chicago 1904, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, aged 64 on the staffs of St. Luke's Hospital Chicago and the Highland Park Hospital, where he died, August 5, of bronchopneumonia.

James Joseph Rowland Highlands, N. J., Atlantic Medical College Baltimore 1909 member of the Medical Society of New Jersey served as a captain with the American Expeditionary Forces during World War I, formerly served as mayor of Highlands and as a school physician, for many years consulting physician at the Monmouth Memorial Hospital, Long Branch aged 56, died July 31, of coronary thrombosis.

Carl Charles McClelland @ Detroit, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1910, specialist certified by the American Board of Ophthalmology, member of the American Academy of Ophthalmology and Otolaryngology fellow of the American College of Surgeons, for many years on the staff of the Grace Hospital, aged 62, died, July 29, of cerebral hemorrhage.

John Knox Musgrave @ Pittsburgh, University of Pennsylvania School of Medicine, Philadelphia, 1919, specialist certified by the American Board of Anesthesiology, Inc., member of the American Society of Anesthetists, Inc. for many years chief anesthetist on the staff of the Western Pennsylvania Hospital aged 55, died August 12, of accidental rupture of the intestine.

Max Kaplan, Memphis, Tenn. Memphis Hospital Medical College 1912 member of the Tennessee State Medical Association served overseas as a captain in the medical corps of the U. S. Army during World War I aged 51, on the staffs of the Methodist Hospital St. Joseph Hospital and the Baptist Memorial Hospital where he died, August 8 of carcinoma of the lung.

Harriett C Waite Van Buren Peckham, Brooklyn, New York Medical College and Hospital for Women Homoeopathic New York, 1890, formerly adjunct professor of obstetrics at her alma mater, at one time visiting gynecologist and surgeon to the Memorial Hospital, aged 81, died August 26, in the Kings County Hospital of injuries received when struck by a trolley.

Samuel Rodin, Winnipeg, Man., Canada, Manitoba Medical College, Winnipeg, 1916 was a lecturer in medicine at his alma mater, served overseas as a captain with the Royal Canadian Army Medical Corps during World War I, aged 47, member of the honorary attending staff of the Winnipeg General Hospital, where he died, June 29, of carcinoma of the colon.

Louis Franklin Curtis Bradshaw, Neb., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902, member of the Nebraska State Medical Association, aged 63, died, August 6, in the University of Nebraska Hospital Omaha, of carcinoma of the rectum and thrombosis of the ilio-colic artery and superior mesenteric vein.

W. Harry Glenn, Buffalo, Johns Hopkins University School of Medicine Baltimore, 1902, formerly demonstrator of pathology at the University of Buffalo School of Medicine, aged 68, died, July 26, in the Buffalo General Hospital of atherosclerotic aneurysm of the abdominal aorta with perforation, coronary sclerosis and chronic peptic ulcer.

John Bell Howe, Hines, Ill., Chicago Homoeopathic Medical College, 1895, served as a captain in the medical corps of the U. S. Army during World War I, aged 70, for many years served as chief of the hospitalization unit of the Veterans Administration Facility, where he died, August 17, of coronary occlusion.

Henry Powers Hammond, Menlo Park, Calif., Albany (N. Y.) Medical College, 1899, member of the Medical Society of the State of Pennsylvania, formerly on the staff of the Franklin (Pa.) Hospital, aged 71, died, August 2, in the Franklin Hospital, San Francisco, of postoperative pulmonary embolism.

Harry Wall, Middle River, Md., University of Virginia Department of Medicine Charlottesville, 1904, member of the Medical and Surgical Faculty of Maryland, served in France as a captain in the medical corps of the U. S. Army during World War I, aged 61, died, July 15, of coronary occlusion.

Lucius Lamar, Dawson, Ga., Atlanta Medical College, 1892, Medical Department of Tulane University of Louisiana New Orleans, 1893, member of the Medical Association of Georgia, served in the medical corps of the U. S. Army during World War I, aged 70, died, June 9, of hemiplegia.

John Wesley Shupert, Warsaw, Ky., University of Louisville (Ky.) Medical Department, 1910, member of the Kentucky State Medical Association, formerly served as county coroner, aged 56, died, July 28, in the William Booth Memorial Hospital, Covington, of carcinomatosis.

Faus Peter Silvernale, Great Falls, Mont., University of Minnesota Medical School Minneapolis, 1920, member of the Medical Association of Montana, aged 52, president of the staff of the Columbus Hospital, where he died, August 8, of coronary thrombosis.

John Henry Weaver, Hope, Ark., Louisville (Ky.) Medical College, 1881, formerly served as health officer of Hope, aged 84, on the staff of the Josephine Hospital where he died, July 15, of heart disease following an operation for acute appendicitis.

Charles James White, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1923, associate professor of physical diagnosis at his alma mater, on the staff of the Hahnemann Hospital, aged 44, died, July 13, of chronic glomerular nephritis.

Margaret Brinkerhoff Williams, Miami, Fla., Medical College of Virginia Richmond, 1938, member of the Medical Association of Florida and of the American Society of Anesthetists, Inc., aged 43, died, July 29, in the Victoria Hospital of pneumonia.

Ellis Harbert, Stockton, Calif., Vanderbilt University School of Medicine, Nashville, Tenn., 1893, member of the California Medical Association, aged 76, died, July 16, of cholelithiasis with obstruction of the common duct and cirrhosis of the liver.

George Stanford Hensyl, Mahanoy City, Pa., Jefferson Medical College of Philadelphia, 1909, on the staffs of the

Ashland (Pa.) State Hospital and the Locust Mountain State Hospital Shenandoah, aged 55, died, July 27, of coronary thrombosis.

Rorbye Hansen, Monticello, Minn., University of Minnesota Medical School, Minneapolis, 1928, member of the Minnesota State Medical Association, served as chief pharmacist mate during World War I, aged 45, died, July 21, of heart block.

Albert Wilson Greene, Schenectady, N. Y., New York Homoeopathic Medical College and Flower Hospital, New York, 1909, specialist certified by the American Board of Otolaryngology, aged 54, died, August 11, of coronary occlusion.

Harold Elliott Bates, New Lebanon, N. Y., University of the City of New York Medical Department New York, 1892, aged 72, died, July 26, in St. Luke's Hospital, Pittsfield, Mass., of coronary occlusion and arteriosclerosis.

Charles A. Schladermundt, Buffalo, Niagara University Medical Department Buffalo, 1889, an Affiliate Fellow of the American Medical Association, aged 89, died recently of cerebral hemorrhage and arteriosclerosis.

William Harvey King, Scarsdale, N. Y., New York Homoeopathic Medical College, New York, 1882, formerly dean and professor of electrotherapeutics at his alma mater, aged 81, died, July 24, of coronary occlusion.

Oliver C. Engle, Yardley, Pa., University of Maryland School of Medicine, Baltimore, 1887, aged 85, died, July 12, in the Mercer Hospital, Trenton, of complications following fracture of the hip received in a fall.

Louis Joseph Lilienblum, Brooklyn, University and Bellevue Hospital Medical College, New York, 1911, member of the Medical Society of the State of New York, aged 57, died, July 4, of coronary occlusion.

Amesbury Lee, Pickrell, Neb., John A. Creighton Medical College, Omaha, 1910, member of the Nebraska State Medical Association, aged 59, died, July 29, in a hospital at Lincoln of acute hemorrhagic pancreatitis.

Lewell T. Genung, Ithaca, N. Y., Cornell University Medical College, New York, 1905, served during World War I for fifteen years health officer of Ithaca, aged 72, died, July 14, of cerebral hemorrhage.

Thomas Cruickshank, Vermillion, S. D., Barnes Medical College, St. Louis, 1899, member of the South Dakota State Medical Association, aged 84, died, August 5, in a hospital at Yankton of diabetes mellitus.

Otto Wilhelm Freitag, St. Louis, American Medical College, St. Louis, 1904, aged 77, died, July 19, in St. Louis County Hospital of injuries received when struck by an automobile while crossing the street.

Robert Ray Fox, Byron, Mich., Detroit College of Medicine, 1906, village president, served as a captain in the medical corps of the U. S. Army during World War I, aged 72, died, July 13, of coronary thrombosis.

Paul Revere Burroughs, Santa Monica, Calif., State University of Iowa College of Medicine Iowa City, 1906, for many years director of health for the schools, aged 60, died, July 1, of coronary thrombosis.

James Aaron Thorn, Vina, Ala., Medical College of Alabama, Mobile, 1903, member of the Medical Association of the State of Alabama, aged 67, died, July 24, in a hospital at Tupelo, Miss., of appendicitis.

William C. Conley, Ironwood, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890, member of the Michigan State Medical Society, aged 75, died, July 5, of coronary occlusion.

James Henley Mills, Mayesville, S. C., Medical College of the State of South Carolina, Charleston, 1907, member of the South Carolina Medical Association, aged 61, died, July 17, of cerebral hemorrhage.

James Walker Curry, Rome, Ga., Southern Medical College Atlanta, 1897, Jefferson Medical College of Philadelphia, 1898, fellow of the American College of Surgeons, aged 67, died recently of myocarditis.

Walter Joseph La Marche, Cambridge, Mass. (licensed in Massachusetts by years of practice), member of the Massachusetts Medical Society, aged 80, died recently of angina pectoris and arteriosclerosis.

John Malcolm Beck, Louisville, Ky., Hospital College of Medicine, Louisville, 1905, aged 62, died, July 20, in the Veterans Administration Facility, Hines, of carcinoma of the pharynx with metastases.

Charles Sanford Williams, Norman Park, Ga., University of Louisville (Ky.) Medical Department, 1880, member of the Medical Association of Georgia, aged 83, died, July 27, of valvular heart disease

James Renwick Tweed, Marissa, Ill., Chicago Homeopathic Medical College, 1886, formerly mayor of Marissa, aged 87, died, July 26, in St. Elizabeth's Hospital, Belleville, of infected varicose ulcer

John Dearborn Hastie, Grand Rapids, Mich., Columbia University College of Physicians and Surgeons, New York, 1904, aged 64, died, July 9, in the Blodgett Memorial Hospital of heart disease

Orlie Parker, Wabash, Ark., Memphis (Tenn.) Hospital Medical College, 1912, member of the Arkansas Medical Society, aged 60, died recently in a hospital at Helena of cerebral hemorrhage

Winthrop Warren Butman, Denver, University of Missouri School of Medicine, Columbia, 1897, member of the Colorado State Medical Society, aged 71, died, July 8, of coronary sclerosis

Presly C Funk, Bridgeport, Texas, University of Louisville (Ky.) Medical Department, 1894, local surgeon for the Rock Island Railroad, aged 82, died recently of cardiovascular vascular disease

Roy Harvey Freeman, Chicago, Loyola University School of Medicine, Chicago, 1917, served in the medical corps of the U. S. Army during World War I, aged 55, died, August 16, of heart disease

Max Aszman, Chester, Ill., Homeopathic Medical College of Missouri, St. Louis, 1890, for many years a member of the board of health, aged 77, died, July 16, of mitral stenosis and arteriosclerosis

Oscar M. Tinsley, Houston, Texas, Louisville (Ky.) Medical College, 1897, member of the State Medical Association of Texas, aged 68, died, July 22, of hepatitis and hypostatic pneumonia

Krekore H. Mallarian, Fargo, N. D., Detroit College of Medicine, 1900, for many years assistant county physician, aged 71, died, July 17, of diabetes mellitus and cerebral hemorrhage

Tanner Lowry, Cartersville, Ga., Atlanta College of Physicians and Surgeons, 1904, member of the Medical Association of Georgia, aged 62, died, July 6, of carcinoma of the throat

Frank W. Fischer, Covington, Ky., Pulte Medical College, Cincinnati, 1897, formerly on the staff of the Bethesda Hospital, Cincinnati, aged 68, died, July 16, of coronary thrombosis

Robert Laurine Cline, Lakeland, Fla., University of Georgia Medical Department, Augusta, 1902, aged 70, died, July 7, in the Morrell Memorial Hospital of bronchopneumonia

Harry Melorian, Plainview, Neb., Rush Medical College, Chicago, 1896, a founder and on the staff of the Plainview General Hospital, aged 72, died, July 9, of coronary thrombosis

Alden Marland Bush, Toledo, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909, aged 58, died, July 15, of carcinoma of the stomach

Robert T. J. Barber, Washington, D. C., College of Physicians and Surgeons, Baltimore, 1886, aged 80, died, August 8, in Saint George Island, Md., of coronary sclerosis

Neil Patrick Donnelley, San Francisco, St. Louis University School of Medicine, 1929, aged 39, died, July 6, of shock and hemorrhage due to accidental third degree burns

Ella V. Timmerman, Little Falls, N. Y., Northwestern University Woman's Medical School, Chicago, 1893, aged 79, died, July 2, in the Little Falls Hospital of pneumonia

James Joseph Hogan, Vallejo, Calif., Cooper Medical College, San Francisco, 1892, M.R.C.S., England, 1898, aged 69, died, July 14, in Cincinnati of coronary sclerosis

Daniel Fisher Beacom, La Harpe, Ill., Rush Medical College, Chicago, 1894, aged 81, died, August 3, of complications following fracture of the hip received in a fall

Nathan Lowe Burnett, Cambridge, Mass., Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1915, aged 55, died, July 20, of valvular heart disease

William Walter Andrews, Tucker, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1900, aged 73, died, July 18, of carcinoma of the left lung

John P. Conway, Memphis, Tenn., St. Louis College of Physicians and Surgeons, 1915, aged 69, died August 2, in the Methodist Hospital of cerebral hemorrhage

William Henly Joyner, Sandy Hook, Ky., Tennessee Medical College, Knoxville, 1909, aged 66, died, July 18, in a hospital at Lexington of lobar pneumonia

Thomas Henry Amos Jr., New York, Boston University School of Medicine, 1921, on the staff of the Harlem Hospital, aged 49, died, August 9, of heart disease

James Madison Harper, Raleigh, N. C., University of North Carolina School of Medicine, Chapel Hill, 1910, aged 66, died, July 5, of uremia and pericarditis

Walter Dekel Ramsay, Noma, Fla., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1904, aged 74, died, July 7, of bronchopneumonia and paralysis

Harold Levi Baldwin, Jr., N. Y., University of Vermont College of Medicine, Burlington, 1899, aged 65, died, July 1, in Keeseville of acute coronary occlusion

George Columbus Horne, Jonesboro, Tenn., Chattanooga Medical College, 1898, aged 71, died, July 19, of diabetes mellitus and arteriosclerotic heart disease

Ida M. Woolley, Ottawa, Ill., Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901, aged 77, died, July 20, of cerebral hemorrhage

George McArdle Powell, Springfield, Mo., St. Louis University School of Medicine, 1921, aged 52, died, July 15, in St. Johns Hospital of tuberculosis

Alva A. Shanahan, Marion, Ind., Curtis Physio-Medical Institute, Marion, 1894, aged 73, died in July in the Marion General Hospital of heart disease

James Andrew Quinn, York, S. C., Medical College of the State of South Carolina, Charleston, 1942, aged 25, died, August 2, of Hodgkin's disease

J. R. Colyer, St. Petersburg, Fla., Medical College of Ohio, Cincinnati, 1888, formerly bank president, aged 83, died, July 22, of cerebral thrombosis

John William Fitzgerald, Beaumont, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1898, aged 75, died, July 13, of senility

Andrew T. Botts, Glasgow, Ky., Hospital College of Medicine, Louisville, 1891, aged 73, died, July 18, in Wauseon, Ohio, of cerebral hemorrhage

Alvin Kerr Lyon, Glenshaw, Pa., Western Pennsylvania Medical College, Pittsburgh, 1891, aged 77, died, July 25, of arteriosclerotic heart disease

George William Crice, Barlow, Ky., University of Nashville (Tenn.) Medical Department, 1906, aged 69, died, August 5, of cerebral hemorrhage

William Head McClendon, Roanoke, Ala., Medical College of Alabama, Mobile, 1896, aged 70, died, July 28, of heart disease and nephritis

Jay Clement Johnson, Canal Winchester, Ohio, Ohio Medical University, Columbus, 1903, aged 60, died, July 10, of carcinoma of the liver

Casimir John Mikolaitis, Lawrence, Mass., Chicago College of Medicine and Surgery, 1914, aged 58, died, July 7, of congestive heart disease

John Phillip Hickey, San Mateo, Calif., Marion Sims College of Medicine, St. Louis, 1901, aged 68, died, July 21, of coronary thrombosis

T. R. Flaniken, Rogers, Texas (registered in Texas under the Act of 1907), aged 70, died, July 6, in a hospital at Temple of cerebral hemorrhage

DIED WHILE IN MILITARY SERVICE

John Francis Kerr Jr., Indianapolis, Indiana, University School of Medicine, Indianapolis, 1930, member of the Indiana State Medical Association, was called to active duty as a first lieutenant in the medical corps of the U. S. Army, March 10, 1942, and served as a receiving and dispensing officer at the Jefferson Barracks (Mo.) Dispensary, aged 35, died August 18, in the William Beaumont General Hospital, El Paso, Texas, of embolus following the amputation of his legs as the result of a railway accident

Wolfe Zapolan, Columbus, Ohio, Ohio State University College of Medicine, Columbus, 1939, member of the Ohio State Medical Association, was called to active duty as a first lieutenant in the medical reserve corps of the U. S. Army, Sept. 16, 1941, aged 28, was found dead, July 20, in Mayfield Heights

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Cosmetics

The following items are abstracts of stipulations in which promoters of cosmetics have agreed with the Federal Trade Commission to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Amrol Color and Oil Shampoo Treatment—This coal tar hair dye is put out by Lawrence Richard Bruce Inc. and Amrol Inc. Stamford Conn. In a stipulation that they signed with the Federal Trade Commission in December 1941 they agreed to discontinue any advertisements which did not conspicuously bear the warning that their dye must not be used on eyelashes or eyebrows lest it cause blindness and that a preliminary test according to accompanying directions should be made on any person to whom the dye was to be applied because it contained ingredients which might cause skin irritations to certain persons. The stipulation however provided that if the label bore this warning conspicuously displayed the advertising need contain only the statement "Caution Use only as directed on label."

Ardena Sensation Cream Ardena Skin Lotion and Jole de Vivre—These and some other cosmetics were named in a stipulation which the Elizabeth Arden Sales Corporation of New York signed with the Federal Trade Commission in September 1941. In this the concern agreed to cease advertising that Jole de Vivre will give or help to give a firm texture to the skin or change the contour of the face and that Ardena Skin Lotion has a tonic effect upon the skin. The corporation further stipulated that it would cease representing by use of a brand name containing the words "Anti Brown Spot" or "Circulation" or otherwise, that Ardena Sensation Cream formerly known as Ardena Anti Brown Spot Ointment and as Ardena Circulation Cream will remove brown spots freckles or other discolorations or will stimulate or be of value to a sluggish skin or will give one a clear young or fresh skin void of sallowness or stimulate or have any other appreciable effect upon the circulation.

Beauty Glo Cosmetics—These are put out by Beauty Glo Inc. New York which is run by Joseph Adelman William Cotton and Samuel Scheff. In October 1941 these persons stipulated with the Federal Trade Commission to discontinue the following misrepresentations in the advertising that any of their Beauty Glo preparations when applied to the skin will revitalize it help to eliminate freckles have any effect on blemishes pimples coarse pores or blotches penetrate deeply into the pores remove wrinkles reawaken near dead tissues or prevent the hair from falling out.

Black Strand Hair Coloring—The Tan Tan Company Inc. trading as Black Strand Company Chicago stipulated with the Federal Trade Commission in October 1941 as follows that in the advertising of this product it would cease using the words just one application or the word instantly or other terms of similar meaning which in effect would give the impression that a single application was all that was required to cause the hair immediately to assume and permanently to retain a particular shade or color unless such words when used should be accompanied by explanations clearly disclosing that the dyeing process must be repeated to accomplish such results. In an earlier stipulation made with the Federal Trade Commission (June 1941) the concern agreed that its advertising and labels should not fail to carry sufficient warning as to the risks involved in using their dye.

Camille's Mascara—This was represented in the advertising of Camille Inc. Morristown N. J. as a product prepared from a treasured Egyptian formula or a recipe used for centuries by famous beautiful women of the Orient or elsewhere. In December 1941 the Camille concern stipulated with the Federal Trade Commission that it would discontinue such misrepresentations and also any to the effect that its mascara gives the user long or luxuriant eyelashes or improves the quality of the lashes in any way.

Certain Gro "Liquid Hot Oil Treatment"—In August 1941 Louise G. Ramsey trading as Certain Gro Hair Preparations Gty. Ind. signed a stipulation with the Federal Trade Commission agreeing to withdraw these misrepresentations from her advertising that the product is a remedy or cure for baldness that it revitalizes lifeless hair or will recondition stimulate and promote the growth of hair. She further agreed to cease representing through the use of the term "Certain Gro" or similar designations that such preparations will grow hair.

"Country Garden and "Fragrant Meadow" Cosmetics—These are put out by the Herb Farm Shop Ltd. New York. The first named brand includes the Cleansing Cream "Smoothing Cream Under Powder Cream and Refresher the second named brand is used for the Cleansing Cream Astringent Under Powder Cream "Smoothing Cream Under Powder Mist and Bath Essences. In August

1941 the company signed a stipulation with the Federal Trade Commission agreeing to drop from its advertising the names Herb Farm Shop of London and Herb Farm Shop Ltd. and cease using any other words phrases or representations which indicated contrary to fact that any of its products has an English or other foreign origin unless it is conspicuously stated that such preparation is made compounded or packaged (as the case may be) in the United States that any of its products is infused with or contains herbal oils when such is not a fact. The promoters further stipulated that if any such product does not contain a substantial amount of herbal oil the percentage of that oil will be declared.

Cutex and Peggy Sage—These are nail polishes put out respectively by the Northam Warren Corporation and its subsidiary, Peggy Sage Inc. Stamford Conn. and New York. In August 1941 these concerns signed a stipulation with the Federal Trade Commission in which they agreed to discontinue the following misrepresentations that finger nails have pores or are like the skin in structure that the health growth or length of the nails depends on their contact with air or moisture that the nails absorb or give off moisture or that nail defects such as brittleness are due to moisture conditions or lack of moisture that the nail polishes in question applied to the finger nails contain pores or form a porous or meshlike film or coating or are permeable by any appreciable amount of moisture that the use of competitive brands of nail polish smother or seals up the nails or thereby results in brittle splitting or flaking nails and that Cutex and Peggy Sage can be depended on to remain intact on finger nails without chipping peeling or wearing off for any period of time in excess of the period in which such products will remain intact.

Dark Eyes—This is a dye for eyelashes and eyebrows put out by Hec Barth Chicago who traded under the name Dark Eyes. In a stipulation that he signed in September 1941 with the Federal Trade Commission Barth agreed to discontinue any advertisement of Dark Eyes which failed to contain the caution "Prolonged or frequent use of this preparation may result in permanent discoloration of the skin and mucous membrane provided however that such advertisement need contain only the statement Caution use only as directed on the label if and when the label bears the first mentioned caution conspicuously displayed thereon and the accompanying labeling carries adequate directions for the use of the product. This is supplementary to a Cease and Desist Order issued by the Commission in May 1937 against Hec Barth who was then trading as Hec Barth Laboratories and Dark Eyes Laboratories of Chicago. In 1938 another government agency the Food and Drug Administration also had taken action against the concern then doing business from Chicago as Dark Eyes. Specimens taken from interstate shipments of the product were found to contain two poisonous substances ammoniated silver nitrate and pyrogallol which the government declared might have rendered Dark Eyes injurious to users under the conditions of use prescribed in the label. As the company put up no defense the government confiscated the two consignments of Dark Eyes. This case was briefly abstracted in THE JOURNAL Aug. 3, 1940 page 401.

Dervito—That this would correct sagging facial contours clear fatigue lines restore youthful color or facial contours, free the skin from blemishes eliminate dirt from the pores or remove other evidences of age or that it contains healing herbs were misrepresentations which Flene of Vienna Inc. and Elly M. Schnuck of New York agreed to withdraw from the advertising in a stipulation signed in August 1941 with the Federal Trade Commission. They also agreed to cease representing that the formula of Dervito has been used by great physicians for rejuvenation or for freeing the body of destructive poisons and that this cosmetic penetrates beneath the skin operates under the skin with a vacuum action or attacks under skin impurities.

Elmo Special Formula Cream—In August 1941 the Federal Trade Commission accepted a stipulation from the Elmo Sales Corporation of Philadelphia in which this concern agreed to discontinue such advertising misrepresentations as that the use of this product will prevent retard or otherwise affect changes giving rise to wrinkles crow's feet or other lines characteristic of advancing age or do more than temporarily soften or lessen the permanence of such lines or age signals or temporarily correct dryness and redness of the skin.

El Zombu Cream—One Earl B. McKinney trading as Beauty Affiliates New York stipulated with the Federal Trade Commission in November 1941 that he would cease representing that this product is a competent treatment for wrinkles or is capable of preventing or eliminating skin wrinkles. According to the stipulation neither this cream nor any other known product is capable of preventing or eliminating skin wrinkles by its local application.

Frederics Uni Temp Machine—This was advertised by an E. Frederics Inc. of New York distributor of beauty parlor and barber shop equipment as giving the coolest permanent waves of any on the market and the only one using controlled heat. In November 1941 Frederics signed a stipulation with the Federal Trade Commission to discontinue these claims and the representations that he has exclusive patent rights on thermostatically controlled heat for permanent waving that other manufacturers have resorted to substitute temperature control methods or that heaters sold by a certain competitor are not equipped with thermostats.

Fulto Hair Preparations—These were put out by Emma G. Fulton, doing business as Fulto School of Beauty Culture Chicago. In September 1941 this person stipulated with the Federal Trade Commission to discontinue the following misrepresentations that Fulto Hair Grower Plain also designated as Fulto Plain Hair Food will feed the scalp and hair that this preparation and Fulto Hair Grower (Double

Strength) and Gulto Liquid Hair Grower either singly or in combination will grow hair or that they are remedies or cures for dandruff or diseased scalps. Further she agreed that she would cease representing through the use of the terms Hair Grower and Hair Food or any other terms of similar import that such preparations will grow hair or feed the hair and scalp.

Gouraud's Oriental Cream—This is put out by Ferd T Hopkins trading as Ferd T Hopkins and Son New York. In September 1941 Hopkins stipulated with the Federal Trade Commission that he would no longer represent that this cream is used by famous stage and screen stars, prevents sun or wind burn, restores the skin of youth or will preserve the original attractiveness of the skin during swimming, sun bathing or other outdoor sports. Although tests made by different laboratories in 1936 did not show that this cream still contained calomel or any other form of mercury as it formerly had done nevertheless in 1936 there was a report of an injury following its use.

H S G Cosmetics—Under this brand Henry S Gompes Inc of New York puts out lipstick, rouge, face powder, eye shadow and perhaps some other cosmetics. In December 1941 the concern signed a stipulation with the Federal Trade Commission that it would no longer represent its products as being of French origin or permanent in their effect.

Humm—This hair dye is put out by a Humbert Miragia and a William H H Davis operating under the names Hummi Laboratories Inc, Oakland Calif and Durst Manufacturing Company Inc Ltd San Francisco. The dye is made by the Hummi concern and sold through the Durst Company. In October 1941 Miragia and Davis stipulated with the Federal Trade Commission that they would desist from the following advertising misrepresentations: that Hummi will restore or reproduce the true or natural color of the user's hair in forty-five minutes or any other period of time; that the user becomes an expert in applying the dye in a single attempt (unless this representation is limited to qualified beauty experts or hair dyers); that Hummi is an amazing new product and will make all hair soft and silky and will not deteriorate. In an earlier stipulation that Miragia and Davis had signed with the Commission (June 1941) they had agreed to caution the user not to apply Hummi to eyelashes or eyebrows lest it cause blindness and to submit to a preliminary test for possible sensitiveness to the dye.

Lady Esther Face Powder—In December 1941 Lady Esther Ltd of Chicago stipulated with the Federal Trade Commission that it would desist from representing that face powders in general sold in competition with this product contain sand or other gritty minerals not present in the Lady Esther powder and that the use of such competitive products will result in loss of beauty or cause an appearance of age. Also to be discontinued were any similar representations concerning the character, quality or properties of competitive face powders with a tendency to deceive purchasers and disparage such competitive products.

Lady Lennox Hair Coloring—This dye is put out by the Lady Lennox Company of Memphis Tenn. run by a Norman W Siehrns. In a stipulation that Siehrns signed with the Federal Trade Commission in October 1941 he agreed to drop from his advertising the terms new, new discovery and modern or words of similar meaning as descriptive of his product. Further he agreed to discontinue using any representations which might give the impression that the use of this dye will cause all hair including such as may be normally stiff or kinky to become soft, gleaming and silky or that use of the preparation will end gray hair in the sense that as it grows out gray hair will not again appear at the roots or that the product will restore the original color to hair which is turning or has become gray. In a stipulation that he had signed with the Commission earlier in the same year (June 1941) Siehrns had agreed to discontinue any advertisement which failed to warn the user of his product that it must not be used for dyeing the eyelashes or eyebrows because of the danger of blindness and that a preliminary test should first be made according to accompanying directions to determine whether the user might develop skin irritation.

Lucky Heart Products—These are put out by Lucky Heart Company, Memphis Tenn. also trading as Erbru Medicine Company and formerly as Lucky Heart Laboratories Inc. In December 1941 the Federal Trade Commission reported that the concern had signed a stipulation agreeing to discontinue the following misrepresentations: that its Bleaching Cream will make the skin ten or any other number of shades lighter or that through its use one may have as light a skin as desired; that its Double Strength Cream gives the user light smooth skin in the first day; that its Lemon Bleaching and Cleansing Cream bleaches the skin or sinks deep into the pores or brings out dirt and impurities; that its Instant Pink Cream keeps the skin young; that its Vanishing Cream makes the skin firm or beautiful or removes or prevents wrinkles; that its Rosebud Skin Bloom will give the skin new life or youth or prevent skin dryness or that its Coconut Oil Shampoo will prevent scalp troubles. Further the company agreed to cease representing that any of its products will rid the body of offending odors, kill dandruff, stop falling hair or remove pimples or other blemishes; that its product Erbru Lavative contains herbs or roots in their natural state or that its Erbru has any general systemic effect. The company further promised to eliminate the term Coal Breaker from the name of its Coal Breaker Brand Pills as implying that the product will break a cold or relieve feverishness associated therewith. An earlier stipulation was signed in April 1938 by this concern then known as Lucky Heart Laboratories Inc. and one of the provisions was that it would discontinue the word Laboratories in its trade name. In November 1939 the Lucky Heart Laboratories Inc. and two of its officials were fined a total of \$7,000 in a federal court for violating the federal Food and Drugs Act in making interstate shipments of a number of their nostrums whose labels bore false and fraudulent claims. One of these products was the Coal Breaker Pills mentioned above and the government chemists reported that each pill contained about

0.93 grain of rectified with extracts of plant drugs including capsicum and a heptive plus smaller amounts of camphor, a quinine and an iron compound, chalk and tile. This case was designated *Notice of Judgment 30965*.

Malintzin—This is a hair dye put out by Jose Gonzalez and Mrs. Henry (Helene G.) Myers both of Laredo Texas. In August 1941 these persons signed a stipulation with the Federal Trade Commission that they would cease advertising that Malintzin gives permanence of color or using, similar statements that give the impression that this product when applied to gray hair would prevent the hair shaft which subsequently emerges from the hair follicle from appearing in its natural grayness from using the statement imparts a naturalness in any shade of hair and from employing the word harmless or safe as descriptive of their product. As the Commission's stipulation states that Malintzin contains an ingredient (unnamed) which may prove harmful under some conditions of its use or when or if used by certain persons. Earlier in 1941 June 20 the Commission had announced that Malintzin was one of 19 coal tar hair dyes whose promoters had signed stipulations agreeing to carry warnings on their labels to the effect that the person on whom any of these dyes are used should first have a patch test to determine sensitivity to coal tar dyes.

Natural Cosmetics—This was the brand name of a line of preparations put out by A M Zindel of New York who traded as Zindel Laboratories. In August 1941 the Federal Trade Commission reported that Zindel had signed a stipulation agreeing to discontinue certain misrepresentations. Among these were the use of the term Vegetable Wrinkle Cream implying that his products sold under this designation prevent or remove wrinkles or lines; reference to Skin Food and Face Cream as indicating that any of his cosmetics is a skin or face food; the use of the designation Acne Lotion as representing that anything he sold under this name might have value in treating acne; that his Sun Tan Preparations divert the ultraviolet rays absorbed waves or contain a filter screen that the application of Sun Liquid Cream will protect the body from overheating or will shape or mold the body contour or that Lemon Cream bleaches.

Noreen Super Color Rinse—In December 1941 H L Baum trading as Beauty Products Denver stipulated with the Federal Trade Commission that he would cease and desist from representing that this coal tar hair dye gives life to the hair, eliminates itching, does not stain the scalp or fingers, contains more or truer color or is not a hair dye. Still earlier in June of the same year Baum's concern had been one of a large number of companies which had signed stipulations with the Commission agreeing to discontinue any advertisements which failed to carry conspicuously the following: 'Caution: This product contains ingredients which may cause skin irritation on certain individuals and a preliminary test according to accompanying directions should first be made. This product must not be used for dyeing the eyelashes or eyebrows to do so may cause blindness. The stipulation however provided that if the label itself conspicuously displays this warning it will be sufficient to state in the advertisements: Caution: Use only as directed on label.'

Patrol Croco Pads—A stipulation regarding this was signed with the Federal Trade Commission in June 1942 by Herbert Sidney R and Elmer Lipman trading as Velva Supply Company, Velva Beauty Products and Lynns Crowder Company, Detroit. In this they agreed to cease representing that permanent wave pads sold by competitors are made of aluminum foil whereas their own pads advertised as containing neither flannel nor foil were stronger or better than foil flannel pads or stronger than competing pads. According to the stipulation aluminum has not been available for some time for use in the manufacture of permanent wave pads; the pads sold by the respondents' competitors do not contain aluminum foil and the representations that the purchase of the Patrol product results in conservation of aluminum are not in accord with the facts.

Pine Needle Oil Soap—This is distributed by the B J Melville Company, Cincinnati which in November 1941 signed a stipulation with the Federal Trade Commission to cease using the term Pine Needle Oil to designate its soap or otherwise representing that the product contains a substantial amount of pine needle oil.

Rejuvena—This hair dye, also called Rejuven, is put out by the A Rhodes Company Inc, Lowell Mass. which in August 1941 stipulated with the Federal Trade Commission to discontinue the following misrepresentations in the sale and distribution of its product: that Rejuvena has healing properties or will in itself be beneficial to the skin or scalp; that it contains anything of particular value in preventing falling hair; will do more than simply assist in the temporary removal of dandruff; tend to produce a youthful appearance other than to change the color of gray hair or prevent the hair shaft which emerges from the hair follicle after the application of the dye from appearing in its natural grayness. In 1934 the New Hampshire officials reported that after they had banned the sale of the Rhodes dye in that state, among others continuing to lend the Rhodes concern informed them that a different type of coloring would be substituted in the product when sold in New Hampshire.

Studio Girl Shampoo—That this has any effect on hair or scalp beyond a cleansing action on the surface or removes embedded dirt, penetrates the pores or reconditions or revitalizes hair that it enables hair to withstand the glare of studio klieg lights or restores normal characteristics to hair which has been impaired by exposure to such lights or that the product is the official shampoo of any motion picture studio were misrepresentations which the Taylor Rea Corporation trading as House of Taylor Rea, Los Angeles, agreed to discontinue in a stipulation that it signed with the Federal Trade Commission in September 1941.

THE TESTING OF AGENTS AND METHODS FOR THE TREAT- MENT OF HYPERTENSION

To the Editor—The article entitled 'Experimental Observations on the Treatment of Hypertension by Goldblatt and others' (*THE JOURNAL*, August 8) merits amplification. The authors state that since it is now possible to test the effect of renal extracts (and other therapeutic agents) on experimental hypertension in animals they should not be made available for general use until more consistent results have been obtained in many tests on animals with experimental hypertension. It can hardly be disputed that if a given agent or method is efficacious in the treatment of experimental hypertension in animals, it is at least worth a trial in human medicine, but the converse would be true only if it was established that irreversible arterial and arteriolar sclerosis invariably precedes and determines hypertension in man. In this connection the most that Dr Goldblatt has ever contended in his writings is that arteriolar sclerosis 'probably precedes and is often associated with' essential hypertension. He has never denied that nervous influences or other factors as yet undetected may cause spasm of the renal vascular bed nor has he denied that the hypertension so produced would be far different both etiologically and mechanically, from that caused by clamping the renal arteries of dogs. As Friberg has said, whether arteriolar sclerosis in the kidney is cause or effect or both of hypertension" is still an open question.

If we could be sure that essential hypertension in man is, without exception, the counterpart of the experimental hypertension produced by the Goldblatt clamp we would be justified in taking the stand that therapeutic agents which fail to reduce blood pressure in animals are thereby proved worthless in the treatment of human hypertension. But this premise is far from proved. Indeed there are many experimental and clinical observations which cast grave doubt on the wisdom of assuming that structural changes in the blood vessels necessarily antedate the development of hypertension in man or that such changes are always irreversible. Until these doubts have been resolved experiments of the type cited in the present article by Goldblatt and his co-workers are not nearly so valid as the casual reader might suppose.

Dr Goldblatt's contributions to the subject of hypertension are widely recognized and highly esteemed. It would be unfortunate if any reader of his present article were to draw conclusions which he has taken care to avoid. His final statement deserves emphasis: that the true value of his studies and of similar investigations must and will depend on the results obtained in the treatment of human hypertension. The adoption of any other point of view is distinctly hazardous because it is liable to lead to unwarranted pessimism verging on therapeutic nihilism. The search for effective methods of combating or preventing hypertension cannot be abandoned nor should any new agent of promise be discarded until its potentialities have been explored fully in the clinic as well as in the laboratory. I feel sure that Dr Goldblatt shares this view, even though a superficial reading of his article might indicate otherwise.

CARBOHYDRATES IN DIET AND FLATULENCE

To the Editor—In his article "What Causes Flatulence?" (*THE JOURNAL*, September 5), Alvarez describes several disorders and diseases that are often accompanied by flatulence. He says that a failing heart, insanity, anxiety or pain, cholecystitis, colds, the eating of certain foods, plus a few more disorders, may cause flatulence. One is also led to conclude that the mechanism responsible for the flatulence in each of these disorders would be different for each disorder.

During the past four and one half years I have treated patients with peptic ulcer, pseudoulcer, angina pectoris, pseudorachitis, hypertension, recurrent abdominal pain and anxiety states with a diet in which all carbohydrate rich foods are eliminated. Carbohydrate present in 5 and 10 per cent fruits and vegetables was permitted. After a few days and some times after the first meal on such a diet, the flatulence would disappear completely. The patients would be free from flatulence as long as they followed the diet. These observations have been reported in papers published during the past two years.

The observations suggested a common causal mechanism for the flatulence, namely a disturbance in carbohydrate metabolism due to the ingestion of carbohydrate rich foods. I attempted to show that a decreased oxidation of dextrose could result in disordered gastrointestinal motility and secretion. A striking observation was the disappearance of protruding abdomens after a few weeks on the diet and with little or no loss of weight. This indicated that the distention was due to atony of the intestinal musculature a condition readily reversed by the elimination of carbohydrate rich foods. Incidentally, fetor oris disappeared along with the flatulence.

ARTIFICIAL ANTIBODIES

To the Editor—In the August 15 issue of *THE JOURNAL* appears an article on artificial antibodies. I note that you use a bibliography of authors dating from 1927 to the present with the exception of the 1915 Russian authors, who heated toxin with horse serum.

An American scientist, immunologist physician and major (retired) in the Medical Corps of the United States Army Dr Frank M Wood did original researches on this subject in 1912. Many processes are in fact part and parcel of the original method of producing detoxified antigens (or partial antibodies) by this author, namely:

1 The use of trypsin by Sdrawosmisslow and Kimmelstiel is part of the author's process.

2 Addition of alkali and slow return to neutrality, and incubation as used by Pauling and Campbell is part of his process.

Dr Wood now lives at 1751 South La Brea Avenue, Los Angeles. His original researches should be given the recognition he so justly deserves.

Oklahoma Reciprocity Report

The Oklahoma State Board of Medical Examiners reports 9 physicians licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners from February 5 through May 11. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Arkansas School of Medicine	(1938)	Arkansas	
University of Illinois College of Medicine	(1937)	Illinois	
University of Kansas School of Medicine	(1940)	Kansas	
Tulane University of Louisiana School of Medicine	(1936)	Louisiana	
Washington University School of Medicine	(1937)	Missouri	
Woman's Medical College of Pennsylvania	(1930)	Delaware	
University of Texas Faculty of Medicine	(1939)	Texas	
University of Virginia Dept. of Medicine	(1930)	(1939)	Virginia

School	LICENSED BY ENDORSEMENT	Year Grad
University of Manitoba Faculty of Medicine	(1931)	

Louisiana February Report

The Louisiana State Board of Medical Examiners reports the written examination for medical licensure held at New Orleans, Feb. 26-28, 1942. The examination covered 12 subjects and included 100 questions. An average of 60 per cent in each subject was required to pass. Eighty-three candidates were examined, all of whom passed. Twenty-three physicians were licensed to practice medicine by reciprocity. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Stanford University School of Medicine	(1942)*		1
University of Colorado School of Medicine	(1937)		1
Yale University School of Medicine	(1936)		1
Bennett Medical College	(1916)		1

Northwestern University Medical School	(1940)	

Oregon April Report

The Oregon State Board of Medical Examiners reports the written examination for medical licensure held at Portland, April 22-24, 1942. The examination covered 12 subjects and included 78 questions. An average of 75 per cent in each subject was required to pass. Twenty-five candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
College of Medical Evangelists	(1941)*		1
Rush Medical College	(1941)		1
University of Illinois College of Medicine	(1941)		1
University of Minnesota Medical School	(1942)		1
University of Oregon Medical School	(1938)	(1940-2)	20
(1941-17)			
Temple University School of Medicine	(1941)		1

* This applicant completed four years medical work and will receive the M.D. degree on completion of internship.

Arizona July Report

The Arizona State Board of Medical Examiners reports the written examination for medical licensure held at Phoenix, July 7-8, 1942. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Four candidates were examined, all of whom passed. One physician was licensed to practice medicine by reciprocity. The following schools were represented:

School	PASSED	Year Grad	Number Passed
University of Southern California School of Medicine	(1942)		1
Rush Medical College	(1940)		1
State University of Iowa College of Medicine	(1941)		1

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Jefferson Medical College of Philadelphia	(1911)		Florida

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Failure to Diagnose Glaucoma—One of the defendants, referred to hereafter as the attending physician, undertook over a period of years, beginning in 1932, to treat the plaintiff for some eye ailment. On Nov. 10, 1932, the patient complained of watering of the right eye and mhra were removed therefrom. About three weeks later the patient complained of a slight haze over the right eye and more mhra were removed. Three times in 1933 the patient consulted the attending physician, once relative to some impairment of hearing, and on the last visit in 1933 an examination was made of both eyes which indicated that at a distance of 15 feet the vision of both eyes was normal and that a reading glass gave the patient normal reading. The patient was not seen again until 1937. Starting in July of that year and lasting until Sept. 20, 1938, the patient was seen about every three months. On the last mentioned date, according to the attending physician's records, there had been a total loss of vision in the patient's right eye since July 10 of that year and, in the words of the records, "probably detachment of retina. Cannot make out any details of fundus." About six months later the patient consulted another physician who made a diagnosis of glaucoma and performed an operation which seemingly stopped the progress of the mhras and such vision as was left was preserved. The patient then brought a malpractice suit against the attending physician and two other physicians with whom he practiced medicine on a partnership basis. The complaint alleged that the attending physician neglected and failed to diagnose correctly the patient's illness and failed and neglected to treat his eyes for glaucoma and that if ordinary and reasonable care, skill and judgment had been exercised the glaucoma would have been detected and his eyesight saved by a proper operation. After the institution of the suit the attending physician died and his executor was substituted as a defendant in his stead. There was a judgment in favor of the patient and the defendants appealed to the Supreme Court of Oregon.

The defendants contended first that motions that they made in the trial court for a nonsuit and for a directed verdict in their favor, which were denied, should have been granted. These contentions were based essentially on the argument that there was no evidence that during the time the patient was treated by the attending physician he was suffering from glaucoma or that there was any carelessness or negligence in failing to discover the existence of the disease or any failure to give any treatment for the disease, or that because of the failure to discover and treat glaucoma the patient had been damaged. The Supreme Court, however, believed that there was sufficient evidence in the record to prove these facts. There was testimony, said the court, that in cases of glaucoma when the tension goes above the upper limit of normal the eye is in danger of gradually losing its vision and that when the patient ceased going to the attending physician the tension in the left eye was above the upper limit of normal. It was further testified by one of the defendants that eye specialists treating a person past 50 years of age, such as the patient was, suffering from an impairment of vision were on the lookout for glaucoma, particularly so when the vision continually gradually deteriorates and becomes worse. It further appeared that the blurring and impairment of vision was continually present in the plaintiff during the course of treatment. The record, said the court, indisputably reflects the fact that the patient's condition grew slowly but steadily worse and that the patient was not treated for glaucoma. It is shown with equal certainty that when the patient followed the advice of the physician to whom he went in 1939 and submitted to an operation for glaucoma the progress of his malady was stopped and such vision as he then had was preserved. In other words, treatment recognized as proper in cases of glaucoma brought favorable, prognosticated results while treatment, not based on a diagnosis that the case was one of glaucoma, was unavailing. In view of this state of the record,

the court held that there was substantial and competent evidence that when the patient was under the attending physician's care he was suffering from glaucoma and that the treatment given resulted in progressive deterioration in and partial destruction of the patient's vision. Since the treatment based on the second physician's diagnosis checked the deterioration and preserved the impaired vision which the patient then had, the court held that it is plainly within the province of a lay mind to deduce from those facts that the attending physician's diagnosis and treatment were radically wrong and that the treatment of the second physician was right.

Under the circumstances, continued the court, we see no reason for holding that it required the direct testimony of some member of the medical profession to the effect that the diagnosis and treatment were wrong in order to sustain a finding by the court to that effect. Furthermore, the testimony of the second physician disclosed that the approved method of testing the eyes, to determine whether a glaucomatous condition is present is by the use of a tonometer. No such test was made. This failure presented a question for the jury to determine whether the attending physician in the exercise of the degree of care imposed on him should have used the method described by the second physician.

The defendants finally contended that the right of the patient to sue in this case was barred by the statute of limitations. The statute of limitations, said the Supreme Court, generally begins to run in malpractice actions from the time of the occurrence of the malpractice of the physician, but in the case of continuing treatment such as here the statute of limitations does not begin to run until the discontinuance of treatment. A continued treatment, when shown to have been based on a mistaken diagnosis and not of a character employed by the medical profession in dealing with cases of glaucoma, constitutes a continuing tort causing the statute of limitations to start only when such treatment ceases. The treatment in this case ceased in September 1938 and suit was started July 23, 1940. For this reason, said the court, we hold that when this action was instituted the statute of limitations had not run with reference to any damage the plaintiff may have suffered by reason of the glaucomatous condition of either or both of his eyes.

The judgment in favor of the patient was accordingly affirmed.—*Shriss v Chamberlain*, 126 P (2d) 28 (Ore. 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Size of Heart as Guide to Treatment of Addison's Disease with Desoxy corticosterone Acetate. T. H. McGivach. New York—p. 99.

Acute Coronary Occlusion.—Woods and Barnes evaluate the possible contributing factors which caused 60 of 128 patients with coronary occlusion to die within six weeks while the others survived the immediate period. The average age of the patients was 55 years; the average age of the patients who survived was 51.3 years as compared to 59.2 years for those who died within the immediate period. The immediate mortality of patients who had acute coronary occlusion after 60 was approximately twice that of those before 60. The ratio of men to women was 5.4:1, but the immediate mortality among the males was 41.7 as compared to 75 per cent among the females. This is explained by the fact that most men have acute coronary occlusion before 60 whereas most women are afflicted with it after 60. The immediate mortality among those patients who had anterior apical infarcts and those who had posterior basal infarcts was the same—42 per cent. However, if it was impossible to locate the infarct by the electrocardiographic pattern which it produced the immediate mortality was 81.8 per cent. The appearance of ventricular extrasystoles after acute coronary occlusion is an unfavorable sign, for if these ectopic beats occur often they apparently have a tendency to increase in frequency until ventricular tachycardia is produced which may be followed by ventricular fibrillation and death. Electrocardiograms of the sequence of events after ventricular extrasystoles are presented. In such cases ventricular fibrillation may ultimately cause death, although its actual existence may not be demonstrated. Rapid and progressive myocardial failure immediately followed the acute coronary occlusion and caused the death of 15 of the 60 patients within the immediate period. When a large septal infarct is present as was the case in 5 of these 15, myocardial failure becomes manifest within a relatively short period and progresses rapidly. Massive pulmonary emboli occurred in 6 of the 60 patients who died within the immediate period.

Atheromatosis of Mitral Valve.—Hellwig examined the mitral valve in 100 necropsy cases with atheromatosis. Frozen and paraffin sections of the cusps were stained with sudan III and hematoxylin, with hematoxylin and eosin, and orcein and van Gieson. The youngest subject from whom valves were obtained was 2 years old, the oldest was 87. On the basis of his data the author accepts Amitschkow's view that precipitation of lipoids in the ground substance is the primary event in atherosclerosis and is not preceded by degeneration of the tissue.

Lipoids enter the leaflet with the nourishing blood plasma in colloid solution. The localization of the atheromatous lesions on the ventricular side of the leaflet refutes many etiologic theories and suggests the importance of mechanical factors. The nourishing fluid in the ventricular layers of the mitral leaflet is subjected to percussions and repercussions during each systole, and precipitation of lipoids occurs by mechanical disturbance of their colloidal state in the ground substance. While precipitation of lipoids, formation of cholesterol crystals and deposition of calcium occur in atheromatous heart valves just as in blood vessels, proliferative changes are absent, owing to the lack of blood vessels in the ventricular side of the mitral leaflet.

Reimmunization Against Diphtheria—The data from 808 children reimmunized for diphtheria, according to Voll and Bunney, show that diphtheria antitoxin immunity, regardless of the immunizing procedure is not permanent and that with time the antitoxin content of the blood is reduced. The reduction of antitoxin content, though slow, is definite and progressive. Reimmunization with fluid toxoid or alum precipitated toxoid is extremely effective, one small dose produces a response in a satisfactory proportion of children. There were no general allergic reactions and the local reactions were not severe enough to discourage reimmunization. Previously immunized children who had lost all demonstrable antitoxin responded much better to a single injection than children not previously immunized and without demonstrable antitoxin. Reimmunization of children five or six years after their immunization in infancy would maintain a satisfactory level of blood antitoxin. Alum precipitated toxoid was somewhat superior to fluid toxoid for reimmunization, its comparative effectiveness as a primary immunizing agent was much more striking. Immunization in early childhood and reimmunization on the child's entrance to school should approach complete eradication of diphtheria.

Hemograms in Pulmonary Tuberculosis—Stobie and his colleagues investigated the possible prognostic value of the regular examination of blood of 243 tuberculous subjects. Only 2 were less than 15, and 17 were less than 18. A control series consisted of contact persons and ones complaining of lassitude or other symptoms suggesting pulmonary tuberculosis. The most prominent feature in the hemogram was the leukocytosis and the shift to the left. Usually this increased as the disease advanced, and frequently some restoration toward normal took place as the patient got better. However, there were so many exceptions to this rule that the degree of leukocytosis

cannot be taken to indicate the extent seriousness or activity of the disease in every patient. No absolute lymphocytosis was demonstrated. The percentage of the lymphocyte count was in most instances determined largely by the size of the neutrophil percentage. No other factor of the count was constantly affected by the tuberculous process, nor could any factor in the count be relied on to assess the changes in or progress of the patient. It could not be used in any way for immediate or long term prognosis. A secondary anemia was demonstrated in several patients. Its greater incidence in young adults and middle age suggests that it may be an important etiologic factor and therefore worthy of further study.

Management of Minimal Tuberculous Lesion—Because of the controversy as to whether collapse measures are or are not to be instituted immediately, the 185 cases with minimal lesions seen in the Hudson County Tuberculosis Hospital and Clinics between 1930 and 1939 inclusive were analyzed. On the basis of the data obtained, Kruger and his associates are in agreement with the advocates of early collapse therapy in dealing with advanced tuberculosis. In the minimal stage of the disease and as an initial procedure they strongly endorse what Minor advanced in 1928 namely that rest is the most essential of all therapeutic measures. Arrest of the disease through such treatment occurred in 78 per cent of the series. There were twice as many recurrences among patients managed in the clinic or at home as in the hospital or sanatorium. Collapse therapy is indicated for these patients only when the lesion progresses, when positive sputums are recovered and fail to reverse after a liberal period of bed rest, or when hemoptysis is present. When collapse became necessary in the hospital cases, a free pleural space was obtained in all but 1 instance weeks to months after admission.

Tuberculin Reaction in Tuberculosis During Pregnancy—Lichtenstein attempted to determine whether pregnancy in a tuberculous patient causes anergy to tuberculin. From 1932 to 1941 82 such patients with eighty-four pregnancies were encountered among the 8000 tested at the Municipal Tuberculosis Sanatorium of Chicago. The data indicate that the term "anergy of gravidis" is far from correct. In no instance was a pregnant tuberculous patient completely insensitive to tuberculin. Only a mild depression of sensitivity occurred in the third trimester in about a fourth of the patients. Pregnant women usually react at the 1:1000 level instead of the expected 1:10000 level. Many show only a decrease in the size of the reaction to the same dilution. Such a change cannot be termed anergy. The depression of allergy may probably be accounted for by the additional tissue (fetus, uterus and placenta) to take up the sensitizing agent. This does not explain why some patients maintain a high level of reactivity throughout pregnancy and why the sensitizing agent does not sensitize the fetus. It may be that the sensitizing antibody cannot pass the placental filter or that the tissues of the fetus are not susceptible of being sensitized because of their early stage in the evolutionary process.

Transfusion of Conditioned Universal Blood—Among one hundred and seventy-six transfusions of O blood to which anti A and B substance was added given 147 patients, reactions followed in 53. The patients were closely watched by Klendshoj and his associates for twenty-four hours for any subjective or objective signs of reactions particularly chills, rises in temperature or pulse rate, icterus and hemoglobinuria. Icterus and hemoglobinuria were never encountered. Thirty-nine transfusions were accompanied by a rise in temperature which was attributed to the patient's general condition and not to the transfusion. The reactions of the remaining fourteen transfusions given to 10 patients seemed unquestionably to have been precipitated by the transfusion. Five of the patients belonged to blood group A, 4 to group O and 1 to group B. In none of the cases were signs of agglutination or hemolysis observed. Temperature increases between 2 and 4 degrees F followed four of the transfusions and the increase after the other ten exceeded 4 degrees F and chills were also present. It is likely that these fourteen reactions were mainly caused by pyrogens. Therefore no reactions were ascribable to the conditioning of the transfused blood with A and B specific substances which render blood extremely low in isoantibody titer. The conditioning of blood makes it possible for smaller hospitals to maintain a blood bank with O blood exclusively. Such blood may be kept ready and immediately available for any civil or war emergency.

Acute Coronary Thrombosis in Industry—Direct nonpenetrating injury of the chest can produce nonfatal disabling damage to the heart. Leinoff reports 17 cases of such injury for which compensation claims were made. The resulting disability is due to a combination of structural and functional changes. The clinical picture resembles coronary occlusion, from which it is to be differentiated by the history. Electrocardiograms usually show changes associated with acute lesions. The syndrome should be considered with any injury of the chest. All but 1 of the patients were males. Only 2 patients were less than 40. The actual nature of the work was not as important as the kind of accident. The injuries were evenly divided between the light and the heavy industries. The injury was an important etiologic factor in 15 and only incidental in 2. The chest of 5 was injured by heavy objects, of 6 by striking a hard surface and of 4 in automobile accidents. Nine patients showed external signs of injury. However, their absence does not preclude cardiac damage. During injury to the chest the heart may (or may not) be violently thrown against the bony parts, actually compressed torn from its attachments, have its chambers burst open, be jarred, have the blood forced back into the ventricles or prevented from leaving by compression or be bruised by the pressure of fractured bones. In any given case one or all of these factors may operate. The resulting damage is a combination of structural and functional changes, which do not necessarily parallel each other. Minor lesions probably escape clinical detection because cardiac damage is not suspected and proper diagnostic measures are not taken. After the acute phase the signs and symptoms depend on the amount of residual damage, the degree of healing and the efficiency of the reestablished circulation. Thus the picture is the same as in coronary occlusion and can be differentiated only by the history. If the basic lesion is acute cardiac damage, serial electrocardiograms

should show changes immediately after the injury. Those with a moderate degree of cardiac damage probably recover without any impairment of function. Most of the author's patients showed a residual disability which varied from total to partial loss of efficiency.

Supratentorial Disease—Elsberg and Spatz used the blast and stream injection of odorous substances into the nasal passages as a quantitative olfactory test on 1,000 patients suspected of or suffering from verified intracranial disease. Localization of intracranial lesions by the test is based on the combination of the minimal identifiable odor and on the duration of olfactory fatigue following the test. The olfactory functions of 341 patients were undisturbed. Unilateral or bilateral elevation of the value for the minimal identifiable odor alone occurred in 38 to 45 per cent of patients with lesions in or around the frontal or temporal lobes. When patients with diffuse disease and those for whom a clinical diagnosis had not been made were excluded the figures were 71 to 78 per cent. On the basis of fatigue the lesions were correctly localized in 54 and incorrectly in 18 per cent. The tests were of no value for localizing tumors or other lesions in the posterior cranial fossa. In 103 of 251 patients with verified localized intracranial lesions the olfactory tests correctly localized the lesion and in 130 localization was incorrect. Localization was correct in 22 of 193 patients with supratentorial tumor, in 74 per cent with tumors in or around the frontal or temporal lobe and in 32 per cent with tumors in or around the parietal or occipital lobe of the brain. There was a tumor in or around the frontal or temporal lobe of the brain in 91 per cent of patients with complete anosmia. There was unilateral or bilateral elevation of the value for the minimal identifiable odor without prolonged fatigue in 40 per cent of patients with pituitary tumors and in 68 per cent of patients with nearby pressure signs (defects in the fields of vision). A comparison of the olfactory tests of 115 patients with idiopathic grand mal attacks with their encephalograms shows that the test was normal in 58, diffuse in 28, localizing in 19, anomic in 8 and questionable in 2. The respective figures were obtained from a study of the patients' encephalograms 72, 10, 26, 0 and 7.

Postpartum Hemorrhage—The effect of temporary occlusion of the abdominal aorta on the functions of the spinal cord were observed by Strauss when he found it necessary to compress the abdominal aorta in order to control a severe postpartum hemorrhage. This little used obstetric procedure may be accomplished by various methods, one of which is the application of an abdominal tourniquet, the so-called Monburg tube. Little is known in this country about the possible harmful effects of this procedure. In the case reported by Levy and Strauss, myelopathy resulted from the occlusion. Despite the prolonged aortic compression (for forty-five minutes and then intermittently for two hours) the resulting paraplegia disappeared over a period of months, but certain sensory disturbances persisted. At the last examination eighteen months after the occlusion the gait was normal but somewhat guarded owing to a conscious fear of falling. The motor power in both lower extremities was

excellent. There were no muscular atrophies. Knees and ankle jerks were absent on both sides. Subjective and objective sensory disturbances were present below the groins. The patient complained of spontaneous "soreness" over the anterior surfaces of the thighs. The objective sensory disturbances involved mainly the first four lumbar segments bilaterally, although the fifth lumbar and the first, second and third sacral segments were slightly involved. There was hypesthesia over the anterior surfaces of both thighs and legs, hyperalgesia and hyperpathia in the same areas, except for the right leg which was hypalgesic, and thermohypesthetic posteriorly and anteriorly over both legs. Intestinal function and control were good but some urinary urgency was still present with incontinence at times. The persistence of sensory disturbances and the reflexes indicate that pathologic alterations are still present. Further observation will probably reveal an unpredictable degree of irreversible residual disturbance.

Eosinophilic or Solitary Granuloma of Bone—Since 1930 Green and Farber have studied 13 children who suffered from solitary or multiple destructive lesions of the bone without clinical or roentgen evidence of visceral disease. These lesions appeared to be identical with what has been recently described as "solitary granuloma" and "eosinophilic granuloma." From a study of material removed at biopsy from 10 of the patients Farber concluded that these benign destructive lesions of bone do not constitute a new disease but represent a variant of Hand-Schüller-Christian disease; certain forms of xanthoma

and Letterer-Siwe disease are other examples. The 10 children were all less than 12 years of age. Roentgenographically, single lesions simulated bone cyst, osteomyelitis or a malignant growth. Multiple lesions suggested multiple myeloma or malignant neoplasms, but in the roentgenograms they were indistinguishable from Hand-Schüller-Christian disease. There was little general illness. The symptoms were attributable mainly to the local process. Ordinarily the lesions healed promptly after roentgen irradiation and, on occasion, after curettage. Nine of the 10 patients were well three to ten years after they were first observed and 1 had died; the details of the death are not known. Despite the excellent apparent outcome of the treatment of the 9 patients, if the suggested relationship to Hand-Schüller-Christian disease exists the prognosis should be guarded and the possibility of visceral lesions should be kept in mind.

Sulfonamides in Traumatic and Infected Wounds—From an analysis of 121 cases of chronic bone infection, 47 of old compound fractures with infection and 270 fresh compound fractures Baker deduces that local use of sulfonamides helps to combat infection only when the fundamental rules of wound hygiene are being followed. The one danger of their use is the false security that may be acquired at the sacrifice of established surgical principles. Of the 242 fresh compound fractures treated surgically with local application of sulfanilamide, 192 healed without infection while in 50 there was some postoperative infection. Sulfathiazole was used in 28 and only 3 of these showed any postoperative infection, 1 of these 3 patients was operated on twelve hours after a previous closure. Of 252 cases with primary closure, some degree of postoperative infection occurred in 47. Internal fixation was used in 126, 90 of which healed cleanly and 36 became infected. The results as to the time elapsing between injury and debridement and implantation of the sulfonamide showed no variation in the percentage of primary healing between the group treated within the first six hours and that treated within the second six hours. In only 4 cases was an operation performed after a lapse of twelve hours, healing in all 4 was by primary intention. It appears that infection is due to improper debridement and lack of restoration to normal anatomic relationship rather than to the type of injury or to the drug used. In 14 of the 47 old compound fractures sulfanilamide was used in 7 healing was clean and in 7 postoperative infection developed. Five of the 7 that healed were treated by primary closure and 2 by the open method. The wounds in 2 of the 7 with infection were closed and those of 5 were packed. Sulfathiazole was used in the other 33, 10 had some degree of postoperative infection. Of the 23, 17 were treated by primary closure and 6 by the open method. Of the 10, 3 were treated by closed and 7 by the packed method. Saucerization, irrigation, implantation of a sulfonamide and complete closure in 74 cases of chronic bone (osteomyelitis) infection gave the most satisfactory results. In only 20 was there some degree of postoperative infection. However, 7 of these healed later. Sulfanilamide was used in 11, of which 7 healed. Sulfathiazole was used locally in 63 and the wounds of 47 healed cleanly and those of 16 showed some degree of postoperative infection. The closed method was used by 36 of the 47 with clean healing and 11 by the open. Of the 16 with infections the wounds of 5 were closed and those of 11 were packed with petrolatum gauze. The relative lack of improvement from the addition of the sulfonamides to the open method brings up the question as to what result could be obtained in this condition from adequate surgery and complete closure without the drugs. The drugs have brought to light again the necessity of thorough surgical treatment.

Sulfathiazole in Stored Plasma—Novak presents a method of preserving plasma with the sulfonamide compounds. Plasma to which 0.2 per cent of sodium sulfathiazole is added may be kept indefinitely without danger of contamination at room temperature or in the refrigerator. Sterilization will take place in contaminated plasma if it is stored with the sulfathiazole for a few days. Fluid plasma is available for immediate use and the sulfathiazole present in it is no serious objection to its intravenous use. Certain hospitals have instituted the method and are using it with success. The experimental data show both a bacteriostatic and a bactericidal action. In practice blood from the donor may be taken directly into a solution of 3 per cent sodium citrate and 2 per cent sodium sulfathiazole. About 50 cc of such a solution is sufficient for sterilizing 450 cc of blood and makes a final concentration of 0.3 per cent sodium citrate and 0.2 per cent sodium sulfathiazole. The blood may be stored for future transfusions or the plasma may be removed immediately and stored. Outdated whole blood may be used as a source of plasma. The method obviates the more complicated and expensive processes of desiccating plasma or keeping it in the frozen state.

Concurrent Immunization Against Tetanus, Diphtheria and Pertussis—Miller and Saito report concurrent immunization of 100 children against pertussis, tetanus and diphtheria. For comparison 76 other children were given phase I Hemophilus pertussis vaccine and fluid combined toxoids and the 100 children received H pertussis vaccine and alum precipitated combined toxoids. The results of the latter immunization, as determined by Schick tests, tetanus antitoxin titrations and H pertussis agglutination tests and exposures to whooping cough, were satisfactory but the concurrent injection of fluid diphtheria and tetanus toxoid with H pertussis vaccine were relatively poor in tetanus antitoxin but satisfactory with respect to diphtheria and pertussis. For tetanus immunization an interval of three months between the first and second injections of combined alum precipitated toxoid is recommended. A third injection (without diphtheria toxoid) is indicated three or four months later. This dosage may be more than is necessary for

basic immunity, but it is desirable in that a high level of antitoxin is maintained for a year. Such a high level would be important when toxoid reinjection at the time of injury is neglected or impossible.

Soft Curd Homogenized Milk in Infant Feeding—Wolman and his associates fed 843 infants with formulas from milk homogenized by the sonic and the high and low pressure methods and compared the results with those in children fed formulas prepared with boiled pasteurized milk. Carbohydrate was added to each of the four formulas. The incidence of constipation, diarrhea, vomiting and hundred gastrointestinal upsets in all four groups of infants was low and the babies grew and thrived normally. In digestibility and safety the homogenized milks proved as satisfactory as the control boiled milk. Laboratory studies demonstrate that homogenized or boiled pasteurized milk possessing curdling properties lying within the observed range of test values are digested by the healthy, growing baby without producing undesirable signs or symptoms and with every indication of efficient gastrointestinal breakdown and absorption. The curd tension and related values fluctuated with the seasons and were at different levels with each type of homogenized milk, but the changes and differences did not cause detectable clinical disturbances. Therefore it is suggested that a threshold or dividing zone exists which delimits readily digested or soft curd milks from less thoroughly processed milks or from plain pasteurized milk.

Skeletal Changes and Fetal Erythroblastosis—The clinical and pathologic changes in 5 cases of fetal erythroblastosis are discussed by Tollis and his co-workers who state that in 3 there was hydrops in 1 fetus with hemorrhagic manifestations and in 1 although clinically the child appeared normal at necropsy the liver and spleen were enlarged and there was extramedullary blood formation in these organs and in the kidneys. The cord blood of the mothers of all gave negative serologic tests for syphilis. The most striking change in the skeletal system of these 5 infants was a decided increase in density of the bones seen both in microscopic sections and in roentgenograms taken after death. The change consisted in an increase in the number and thickness of the trabeculae. This increase in density in 2 was uniform throughout the entire shaft while in 3 there were zones of decreased density of varying width a short distance below the lattice at the cartilage shaft junction. In 1 there was a band of increased density beneath the zone of rarefaction. The cause for the zones of decreased density is not clear.

Unilateral Renal Disease and Renal Vascular Changes—The records of 193 patients who had a nephrectomy performed at the Mount Sinai Hospital between 1930 and 1940 were studied by Friedman and his co-workers. Thirty per cent of the patients were followed for less than one year and 70

per cent for one to eight years after nephrectomy. The microscopic sections of 183 kidneys available for study were examined by one of the authors without previous knowledge of the patient's blood pressure (the mean of which was no greater in this series than in a comparable control series of patients) and in classification particular attention was paid to vascular changes. Mild arteriosclerosis of the medium size and larger arteries was observed frequently. Pronounced arteriosclerosis, particularly that type seen in malignant nephrosclerosis, was rare. Endarteritic changes were observed in 85 per cent of the patients with chronic pyelonephritis, in 75 per cent of those with renal tuberculosis, in 33 per cent with renal neoplasms and in 64 per cent with hydronephrosis. They were predominant in inflamed or atrophic areas of the kidneys. They appeared to have no relation to the presence or absence of hypertension. Arteriolar sclerosis, in contrast to endarteritis, was found in all portions of the kidneys, irrespective of inflammation or atrophy. Arteriolar sclerosis was present in 42 kidneys from an older age group of patients with a higher mean blood pressure and a greater incidence of hypertension. Of 28 patients with hypertension 23 had renal arteriolar sclerosis. Arteriolar sclerosis in the kidney is recognized as perhaps the most prominent anatomic abnormality in "essential" hypertension. Whether the vascular changes precede the elevation in pressure or are the result is still open to question. Renal arteriolar sclerosis was not a precursor of hypertension in at least half of the patients in whom it developed. This applies only to the vessels in the diseased kidney. The state of the blood vessels in the intact unoperated kidney is not known. However, there is some evidence that in patients with hypertension both the arteriolar sclerosis and the functional disturbance in renal blood flow is bilateral rather than unilateral. After the diseased kidney was removed the blood pressure level remained essentially unchanged in most patients whether they were hypertensive or normal before operation. Hypertension developed postoperatively in 22 per cent of patients who had a normal preoperative pressure. A significant decline in blood pressure occurred in only 7 per cent who had had hypertension before nephrectomy. The incidence of hypertension was higher in the patients who had a good excretory function than in those with poor or no urinary excretion in the diseased kidney. As the removal of the diseased kidney usually does not result in reduced blood pressure, the nature of the renal disease rather than the expectation of lowering the blood pressure should determine the need of nephrectomy.

Surgical Treatment of Hypertension—Woods reviews the conclusions reached in eight years on the effect of bilateral supradiaphragmatic splanchnicectomy and lower dorsal sympathetic ganglionectomy in hypertension. The clinical results of the operation are evaluated from observations in 350 consecutive cases studied postoperatively for nine months to seven years and a comparison is made between the mortality rate of the first 76 of the 350 patients studied five to seven years after operation and 219 medically treated patients studied five to nine years after the first observation. Of the 350 patients 51.4 per cent had a postoperative decrease in blood pressure of more than 40 mm systolic and 15 mm diastolic (of these 37.5 per cent were reduced to "normal"), the blood pressure remained unchanged in 46.2 per cent and was increased in only 2.4 per cent. The best prognosis for reduction was in the age group from 10 to 29 years. The greatest improvement in the eyegrounds occurred in patients who were suffering from the most acute and severe hypertension, i. e., whose eyegrounds showed either angiospastic changes or papilledema. The urea clearance of 181 patients was determined preoperatively and postoperatively, of 112 with a normal preoperative clearance, that of 87 per cent remained normal and that of 13 per cent grew worse. Of the 69 with a decreased preoperative clearance 45 per cent had a normal postoperative clearance, in 6 per cent it was partially improved, in 42 per cent it remained unchanged and in 7 per cent it grew worse. Of the 36 patients with a normal urine concentration before operation, that of 64 per cent remained unchanged postoperatively and in 36 per cent a decreased concentrating ability developed. In the 172 whose urine concentration was decreased before operation, that of 27 per cent returned to normal that of 17 per cent was partially improved, that of 41 per cent was unchanged and that of 15 per cent

decreased. The teleroentgen measurement of 105 patients before operation revealed that the size of the heart of 55 was normal and that of 50 it was increased. Respectively, the heart of 93 and 50 per cent after operation was normal and of 7 per cent it became enlarged and of 14 partially improved, of 32 it remained unchanged and of 4 per cent it showed further enlargement. Fifty-four of 127 had normal electrocardiograms before operation. Following operation 98 per cent remained normal and 2 per cent became abnormal. Of 73 with abnormal preoperative electrocardiograms 29 per cent returned to normal, 25 per cent were partially improved, 41 per cent remained unchanged and 5 per cent showed the abnormality to be increased. Of 277 who had symptoms before operation 39 per cent lost their symptoms completely, 47 per cent were partially improved, 11 per cent remained unchanged and 3 per cent grew worse symptomatically. The preoperative incapacitation of 55 per cent of 182 disappeared, of 26 per cent became partially improved, of 16 per cent remained unchanged and of 3 per cent grew worse. Determination of the mortality rate following splanchnicectomy in the 76 and the 219 patients reveals (1) that surgery has little effect on the survival prognosis of patients whose renal arterioles (and, by inference, systemic arterioles) showed sclerotic changes (2) that the prognosis of those patients with angiospastic arteriolar changes was definitely improved after surgery and (3) that from this difference in prognosis it appears probable that splanchnicectomy in some way releases the generalized angiospasm and thus reduces the peripheral resistance which is causing the elevation and that when the blood vessels are completely sclerotic the operation fails.

Urinary Obstruction in Children—Harrison reports 5 cases of obstruction of the urinary tract in childhood occurring at the vesical neck. The syndrome produced is characterized by albuminuria, chronic interstitial nephritis, stunted growth, possible mental retardation and asexualism, bone changes and uremia. The uremia has been variously described as albuminuria of late rickets, nephrosclerosis, renal infantilism, renal dwarfism, renal rickets, congenital posterior urethral valve causing renal rickets and renal hyperparathyroidism. The cases are reported to emphasize the obstruction of the urinary tract as the primary lesion and to encourage earlier diagnosis with correction if possible. The course is progressively fatal unless the obstruction is relieved before renal damage occurs. Two of the 5 patients died. Of the 4 surgical patients 3 are living. The prognosis of 1 is guarded. This patient has a solitary kidney and infection, while the other 2 are well and free from infection, 1 of these has attained a height of 6 feet with no bone changes and the other 1 is growing 2 inches a year but is still stunted.

Estrogens for Carcinoma of Prostate Gland—The results of treating 7 patients who had carcinoma of the prostate gland with diethylstilbestrol and diethylstilbestrol dipropionate and the cytologic changes induced by these compounds on the prostate gland of 6 of the patients are presented by Kahle and his associates. Generally, regressive changes were observed after treatment in the neoplastic cells, the changes consisted fundamentally of nuclear pyknosis and cytoplasmic vacuolization. As compared to measurements before treatment, the reduction of the nuclear diameters varied from 18 to 55.6 per cent. The therapy promptly relieved pain and urinary symptoms and there was a general improvement in health. Two bedridden patients were restored to activity in four and six weeks, respectively, after treatment was begun. At the last examination all the glands had lost their malignant characteristics. The clinical improvement was also associated with a regression of metastatic lesions to the bones in the 1 patient for whom serial roentgen study was possible, and metastasis to the lymph nodes regressed in the 2 patients who exhibited such lesions. Transient gynecomastia was observed in 1 patient, there were no other side effects.

Local Use of Sulfonamide Drugs—Osgood deduces from controlled quantitative studies by the method of human marrow culture that in equal concentrations sulfathiazole is more effective than sulfapyridine, sulfadiazine or sulfanilamide against any of the common pyogenic organisms and that sulfanilamide is the least effective. In concentrations attained in a saturated solution in a medium similar to tissue fluid sulfathiazole and sulfanilamide are superior to sulfapyridine and sulfadiazine, and sulfathiazole is much less toxic to living human cells in this concentration than is sulfanilamide. None of these drugs are very effective against large numbers of organisms in any concentration attainable. Procaine hydrochloride and para-aminobenzoic acid inhibit the action of the sulfonamide drugs. Local therapy for prophylaxis is indicated whenever there is a break in continuity of the skin in a minimally or potentially infected area. It is also indicated for the control of infection whenever many pyogenic organisms are present at one site. Locally, powdered sulfathiazole seems to be the drug of choice. The administration of sulfathiazole, neoarsphenamine or sulfadiazine to maintain adequate blood levels before operation eliminates the old contraindication to early operation in that organisms are not disseminated into the blood stream or adjacent tissue. Surgical drainage and irrigation with a saturated solution of sulfathiazole in isotonic solution of sodium chloride temporarily reduces the number of organisms so that sulfathiazole powder locally may prove effective. Enough of the powdered drug should be applied to maintain saturation for at least seventy-two hours. Local procaine and probably other local anesthesia should be avoided, as they probably inhibit the action of sulfathiazole. For application to mucous membranes and for areas in which the powdered drug is too drying, the water soluble lubricating jellies are satisfactory. Sodium sulfathiazole should not be used locally, as it has no advantage over sulfathiazole powder and as it is so alkaline that it may cause extensive damage to tissue.

Local Sulfanilamide in Compound Fractures—The experimental and clinical data of the treatment of compound fractures by implanting sulfanilamide powder at the Minneapolis General Hospital from December 1937 to December 1941 are reported by Jensen and Nelson. Experimentally the requirements for effective local antibacterial sulfanilamide therapy are the reduction of the dose of contaminating organisms, excision of all devitalized tissue, complete immobilization of the fragments and appropriate steps to maintain the temperature of the wound at 98.6 F. Clinically the requirements are the same

The overall incidence of infection from all causes in 212 consecutive compound fractures and 15 compound fracture dislocations was 44 per cent. Two of these were distinctly due to secondary contamination of the wound, and 1 was not treated with sulfanilamide. This leaves 7 cases of primary wound infection—infection resulting from contamination at the time of injury. This gives an incidence of 33 per cent. These failures represent lessons of the failure to establish and maintain in the wounds the local conditions essential for the bacteriostatic action of sulfanilamide. In 2 compound fractures of the tibia with extensive skin loss primary closure was attempted, 1 primary infection developing in a compound fracture of the tibia probably resulted from inadequate immobilization and 1 primary infection occurred in a compound fracture dislocation of the ankle joint in which in an attempt to save articular cartilage not all the soiled surface was cut away. The experimental studies and these cases indicate that no compromise with adequate debridement can be uniformly successful regardless of sulfanilamide. The fifth infection occurred in an extensive necrosis of muscle in which it later became apparent that approximation but not immobilization of the fragments was accomplished. The motion of the wire in the bone resulted in destruction of bone and thus inactivated the sulfanilamide, inviting infection. The sixth and seventh infections represent tragedies. Both were severe *Clostridium perfringens* infections associated with hemolytic streptococci. Debridement in both instances was hasty, and examination of the amputated extremities revealed retained foreign particulate matter.

Mechanism of Asphyxial Resuscitation—Further experimental data are presented by Birnbaum and Thompson to show that in advanced asphyxial resuscitation can be effected after respiration had ceased and the circulation was rapidly failing by rhythmic inflation and suction on the lung with an inert gas such as nitrogen or helium—asphyxial resuscitation. Advanced states of asphyxia were produced by obstruction of the trachea or by inhalation of inert—asphyxiating—gases such as nitrogen or helium. If the asphyxiating procedure was not started within twenty to thirty seconds after respiration ceased, spontaneous recovery usually did not occur. However, if within forty-five seconds to two and one-half minutes after respiration ceased suck and blow resuscitation with inert—asphyxiating—gas was applied, resuscitation of the circulation and respiration was accomplished in 85 per cent of instances. The addition of 10 per cent carbon dioxide to the inert gas inhibited resuscitation. Bilateral vagus section before asphyxia was started prevented asphyxial resuscitation. The carotid sinuses are also greatly concerned in this phenomenon. Denervation of the carotid sinus before obstructive asphyxia resulted in a sluggish asphyxial resuscitation, denervation before nitrogen inhalation asphyxia prevented asphyxial resuscitation. Asphyxial resuscitation, which is primarily a reflex phenomenon, is initiated most efficiently by suck and blow resuscitation within safe limits of pressure and is successful in 85 per cent of instances as compared with 15 to 20 per cent by manual artificial respiration with nitrogen inhalation, rhythmic pressure with nitrogen or rhythmic suction on the lung alternating with nitrogen inhalation. These facts suggest that asphyxial resuscitation is primarily a reflex from the vagus endings in the lungs to the medullary centers. The greater rhythmicity and adequate combined inflation and active deflation of the lung by the suck and blow resuscitator apparently more effectively stimulates the pulmonary vagal endings.

Bacteriophage Treatment of Bacillary Dysentery—Compton relates the experience with antidyenteric bacteriophage in Alexandria from 1928 to 1940 and compares the statistics for Alexandria with those for the rest of Egypt where bacteriophage has not been so freely available. In Alexandria the total annual number of cases of dysentery has averaged about 650 and has not decreased to any great extent, but the number of deaths has fallen sharply, the case mortality, which in the earlier years of the period was more than 20 per cent, has not during the last five years exceeded 6.5 per cent. In Cairo on the other hand there has been no such diminution in case mortality which averaged 29 per cent for the years 1936-1938. Neither has the dysentery case mortality curve (amebic and bacillary) for the rest of Egypt shown any decrease. The much more favorable position in case mortality from dysentery in Alexandria than anywhere else in Egypt cannot be due to the better treatment of amebic dysentery, for that is uniform and standardized throughout the country nor is it due to geographic or climatic factors, as the typhoid case mortality rate for Alexandria and for Cairo has not changed appreciably. The only possible conclusion is that the cause of Alexandria's favorable position is the use of bacteriophage therapy for bacillary dysentery. Much more convincing than the statistical evidence is clinical observation which shows the favorable effect of bacteriophage preparations administered early in dysentery of a bacillary nature.

Cross Infection in Scarlet Fever Bed Isolation Wards—The incidence of cross infection with *Streptococcus pyogenes* was compared by Stalker and his colleagues in two groups of patients, one, consisting of 62 patients, was nursed by the bed

isolation method (beds spaced 12 feet apart) and the other, consisting of 74 patients, by the ordinary method in current use for multiple bed wards. Among the 74 patients 10 were cross infected once, 4 two times and 1 three times, giving a cross infection incidence of 20.3 per cent. The respective figures for the group of 64 patients were 12, 2 and zero, and 22.6 per cent.

Merits of Ozone as Aerial Disinfectant—In trying to determine whether ozone could be used as a disinfectant of air borne bacteria, Elford and van den Ende observed that in concentrations (not exceeding 0.04 part per million) it can be breathed over long periods without irritation, but it does not provide any effective protection against air borne bacterial infection.

Retention of Injected Serum in Circulation—Observations made by Sharpey-Schafer and Wallace on the retention of injected serum in convalescent subjects without circulatory disease with stable blood volumes or ones acutely reduced by venesection show that, when the volume is stable, serum tends to leave the circulation and, though it is retained longer than an equal quantity of saline solution by many, in a few it is lost rapidly. Concentrated serum behaves similarly and since no change in plasma protein was detected, there is evidence in some experiments that protein left the circulation rapidly. When the blood volume is acutely reduced by venesection serum injected immediately is retained, but saline solution is not retained under the same circumstances.

Carcinoma of Male Breast—Excluding 4 patients seen in the last fifteen months, 7 of the 20 male patients with mammary cancer observed by Williams are alive and 9 are dead. The average follow up of those alive is four years and four months, while of those dead it is less than two years. Of 5 treated in clinical stage 1 all are alive and free from disease for periods of eighty, eighty, fifty-seven, thirty-six and twenty-four months, 2 of 5 in stage 2 are alive sixty-two and seventeen months after treatment. All 6 in stage 3 are dead, the longest survival being forty months and the shortest six months. The most important factor in prognosis was the anatomic extent of the disease. In early cases local operation together with roentgen therapy is as efficacious as more radical surgery, while in the more advanced stages the only possible treatment is palliation. All patients with stage 3 cancer were treated by radical surgery when both the local condition and the lymph node metastasis had advanced beyond the point at which operation on the female breast would today be considered advisable. The value of roentgen therapy is difficult to assess from the few cases, but the similarity in the microscopic picture of male and female mammary cancer and knowledge of its effect in female tumors, together with the fact that half the author's small series of cases were of a malignant high grade, is an argument for full use of roentgen therapy in combating this disease. The impression is that the prognosis of carcinoma of the male breast is good when the tumor is confined to the breast tissue, in any stage beyond this the prognosis is poor.

Subtoxic Nutritional Disorder in Infants—Tobler describes a typical case of what has been designated as "enteral influenza." The disorder develops gradually with dyspepsia. It appears mostly in nurslings up to 9 months old. At first the disorder seems harmless. The appetite may be impaired. The stools contain neither mucus nor blood and have an alkaline reaction; they increase to from four to seven a day. There may also be vomiting. In spite of dietetic measures the condition of the child begins to deteriorate after several days. There is loss of weight, but the consciousness is not impaired. Gradually the child passes into a twilight state. The color yellow of the stools differs from the golden yellow of the stools of healthy breast-fed infants. With increasing severity, intestinal motility appears. It may become so severe that manifestations of ileus may threaten life. The prognosis is unfavorable. 24 fatalities have been observed among 30 cases. The average duration of the disorder is sixteen days. Increasing quantities of defatted breast milk are recommended. Adequate amounts of fluid can be provided in the form of saccharin sweetened tea. Subcutaneous infusion of isotonic solution of sodium chloride and of metrazol dextrose is also recommended. Care should be taken that the child receives an adequate supply of vitamin C. To prevent a possible failure of the adrenal cortex function the administration of adrenal cortex extract may be advisable. Prostigmine is helpful in counteracting the intestinal motility. The cause of the disorder has not been explained as yet. Bacteriologic and pathologic anatomic investigations have been without success. The author doubts that the disorder is an "enteral influenza." Early diagnosis is difficult because of the uncharacteristic onset. In the advanced stage the symptomatology resembles that of alimentary intoxication in the toxicosis of nurslings, but it lacks the severe onset, loss of consciousness, the so-called great respiration and the high temperatures that characterize alimentary intoxication. Furthermore the two disorders react differently to a fasting treatment during which only tea is given, whereas in alimentary toxicosis it usually leads to detoxication and improvement in the described subtoxic process it is usually without noticeable influence.

Certuna, Plasmochin, Atabrine and Quinine as Gametocides—Aguilar Meza and his associates report mass treatment of malaria with atabrine and plasmochin among certain rural groups in Guatemala. Because the administration of three doses each day involved difficulties, 200 patients were hospitalized and the entire daily dose was given in one dose. The experiment demonstrated the innocuousness of a single daily dose. The method thereafter was practiced in certain plantations. Daily treatments were suspended after six days and the drug was then given once a week, which was adequate to keep the infection down. In spite of some obstacles such as lack of cooperation on the part of the patients and since the beginning of the war the difficulty in obtaining adequate amounts

of atabrine and plasmochin, the campaign against malaria was continued. Studies on the gametocidal action of plasmochin and certuna (diethylamino oxyquinolinodibutane) seem to indicate that the gametocidal action of certuna is similar to that of plasmochin in case of *Plasmodium falciparum*, but less so in the case of *Plasmodium vivax*. The combination of certuna and atabrine in therapeutic doses does not produce toxic effects. Occurrence of cyanosis and bradycardia after certuna in a few cases was apparently due to wrong dosage. The results obtained indicate that treatment with plasmochin or certuna, whether alone or with quinine or atabrine, is generally satisfactory. Negative tests were obtained in 139 malaria patients treated with certuna after four days, compared with 495 days in 132 persons treated with plasmochin, 34 of whom also received quinine or atabrine. The campaign to control malaria has resulted in a decrease in the percentage of infected persons from 15.51 in 1938 to 8.18 in 1939 and 7.66 in 1940.

- *Thiopitogenic Therapy of Burn. I. Stilmann—p. 882

Therapy of Burns—Stilmann believes that the main therapy of emergency in acute burns is that which aims to control acute pain and shock, after which the proper treatment of the burn is administered. The author advises the following therapy: Immediate administration of a narcotic (a hypnotic for infants) and a cardiac tonic, placing the patient in a comfortable bed and keeping him warmed. As soon as the patient is calmed the burn is cleansed. Then it is treated with a solution which is made up with tannin 5 Gm., sodium bicarbonate 1 Gm., mercuric bichloride 0.1 Gm. and distilled water 100 cc. The first intravenous injections of isotonic solution of sodium chloride and the first dose of adrenal extract are administered three or four hours after administration of the emergency therapy. The whole treatment is repeated for five consecutive days, after which it is discontinued with the only exception of the adrenal extract, which is administered for several more days. During the period of administration of adrenal extract alone the burn is treated with an ointment prepared of tannin 25 Gm., boric acid 6 Gm., zinc oxide 3 Gm., sulfanilamide 3 Gm. and petrolatum 50 Gm. The treatment can be used for patients of any age. The pulverized tannin solution, early in the course of the therapy, forms a thin layer over the burn which prevents dehydration and secondary infection of the burn. The ointment favors spontaneous detachment of the scab. Two cases in infants are reported.

- Absorption of Carotene in Human Intestine. B. Eriksen and A. Hoygaard—p. 200

Liver Biopsy in Juvenile Intermittent Icterus—Krarup and Roholm point out that the term juvenile intermittent icterus was applied by Meulengracht to a condition which is apparently identical with the disorder which had been variously referred to as simple familial cholemic physiologic cholemic, physiologic hyperbilirubinemia or constitutional hepatic dysfunction. The differential diagnosis must consider chronic, hereditary, hemolytic icterus. Differentiation is usually possible on the basis of the osmotic resistance of the erythrocytes and of the reticulocyte count. The differential diagnosis is considerably more difficult in cases of chronic hepatitis because a certain number of cases of acute hepatitis evolve into a chronic form with

cirrhosis and intermittent icterus. The method of hepatic biopsy introduced by Iversen and Roholm in 1939 makes possible a microscopic study of liver tissue. The authors review the histories of 5 patients with juvenile intermittent icterus in whom they employed biopsy of the liver. All these patients had their first attack of icterus when they were about 20 years old. These were followed by periodic recurrences. In 3 of the patients biopsy disclosed a normal histologic picture, 2 of the patients had a moderately severe fatty degeneration of the liver, but none of them had the slightest trace of inflammatory disturbances. This indicates that juvenile, intermittent icterus is essentially different from hepatitis. These investigations support the view that juvenile intermittent icterus is due to a functional impairment of the liver. The significance of the detected fatty degeneration has not been ascertained.

Roentgen Therapy of Genitoperitoneal Tuberculosis of Women—Schuennemann states that all women with genital or genitoperitoneal tuberculosis are subjected at the Würzburg clinic to irradiation according to the method of Uter-Menge. Seventy-four cases were treated during the years between 1924 and 1938. Surgical treatment was avoided as far as possible. The results obtained with irradiation in the 74 cases were compared with statistics in the world literature. The comparison discloses a similarity in the results of irradiation obtained at the Würzburg clinic and that reported in the world literature and demonstrates superiority of irradiation over the exclusive surgical treatment.

Irradiation in Endometriosis—Movers reports the results in 6 out of 64 cases of endometriosis treated with roentgen or radium rays exclusively. In 1 case splenic irradiation was employed unsuccessfully because of recurring hemorrhages. Removal of the second ovary effected a cure. Of the 6 patients irradiated, 2 were treated only with rays, the others were operated on and then subjected to postoperative roentgen or radium irradiation. The progress of endometriosis is not always arrested by the exclusion of the ovarian activity. Roentgen castration therefore is not a reliable procedure in endometriosis. Internal endometriosis is difficult to recognize. If it appears in women over 40 years of age, curettage with subsequent radium irradiation promises results about as favorable as does surgical treatment. Irradiation in endometriosis of the ovaries (chocolate and tar cysts) is unsatisfactory. Surgical treatment therefore is to be employed whenever possible. If a second operation becomes necessary on account of a relapse, a total hysterectomy is to be performed and all functioning ovarian tissue removed. Irradiation should be employed only if an operation cannot be done. Irradiation failed to produce definite results in cases of retrocervical endometriosis. In these cases too, operation should be as radical as possible, all ovarian tissue must be removed. Involvement of the rectum does not call for its resection. If ovarian tissue remains either intentionally or unintentionally and symptoms such as hemorrhage and pain recur, irradiation with the carcinoma dose is advisable which generally will prevent further proliferation. Women with endometriosis must be kept under observation for many years. Follow-up examinations should be made at regular intervals. If the patient has not been subjected to radical operation, the prognosis requires caution.

Acta Pædiatrica, Stockholm

- *Dosage and Secondary Effects in Treatment of Children with Sulfathiazole C. W. Herlitz—p. 1
Sporadic Hemophilia and Pseudohemophilia S. Van Crevelde—p. 37
Experimental (Osteodentino) Amelodystrophia Hyperpara Thyreotica in Rats P. F. Sjoquist—p. 59
*Diphtheria, Anatoxin and Tuberculosis G. J. Huet—p. 75
Scarlet Fever and Diphtheria in Finland and Sweden During the Last Decades B. Sonander—p. 96

Sulfathiazole in Treatment of Children—Herlitz reported in a previous paper that children treated with sulfamizamide or sulfapyridine develop mild toxic effects of a short duration. In some, however, considerable disturbances of myelopoiesis may develop. The present paper is concerned with the secondary effects of sulfathiazole particularly on the leukopoiesis. The observations were made on 125 children the majority of whom had acute infections of the respiratory tract. Forty-eight were less than 1 year old, the other 77 ranged in age between 1 and 13 years. The usual dose was 0.1 Gm per kilogram of body weight daily. Within these limits the size of the dose was apparently without influence on the development of secondary toxic effects. The daily dose was usually divided into 5 doses and medication was continued for from three to six days. Secondary toxic effects developed in 26 of the 125 cases (20.8 per cent). Vomiting was observed in 14, neutropenia in 5 and leukopenia in 2. Neutropenia developed after ordinary doses and after brief sulfathiazole medication. The total number of leukocytes was never particularly low before the treatment in cases in which neutropenia developed and leukopenia never developed in these cases. In some cases the number of neutrophil polymorphonuclear leukocytes reached their lowest values several days after discontinuance of sulfathiazole. This indicates the importance of control of the white blood picture for some time after the treatment. In 4 of 5 cases neutropenia disappeared within a few days, but in the fifth case it persisted after one month. The two children who developed leukopenia had been treated with moderate doses of sulfathiazole. It is noteworthy that neither had had a particularly low leukocyte count before the onset of the treatment, one had a neutropenia for several days. The leukopenia disappeared in both a few days after the withdrawal of sulfathiazole. In 2 infants treated with the customary therapeutic doses there developed a toxic granulocytopenic impairment of the bone marrow. A temporary leukopenia and neutropenia developed in 1 case in addition to the granulocytopenia. The author stresses that although the bone marrow may show signs of granulocytopenia the white blood picture may be entirely normal. There need be no neutropenia in the leukopenia produced by sulfathiazole. Impairment of the bone marrow may develop a week after termination of sulfathiazole treatment. The incidence as well as the severity of toxic effects of sulfapyridine and sulfathiazole are about equal. They were comparatively mild in the material examined, but both preparations may affect the leukopoiesis. Toxic impairment of myelopoiesis would be discovered more often if the bone marrow was more frequently examined following sulfapyridine and sulfathiazole therapy.

Diphtheria, Anatoxin and Tuberculosis—Huet shows that contact diphtheria will be found more often in a closed milieu than in children not confined. There are two methods for prevention of the high incidence of diphtheria in children's homes: (1) The spreading of the infection can be prevented by isolating the patients and the carriers, (2) the susceptibility of the contacts can be diminished by active immunization. The efficacy of both is limited. The author gives an account of ten years' experience in preventing diphtheria in a sanatorium for tuberculous children. He shows why mere isolation does not suffice in a semiclosed children's home. Active immunization is therefore indicated, although this method has many drawbacks. The author reports a statistical inquiry on the influence of toxoid injections on susceptibility to infections of the throat and the upper respiratory tract. To prevent complications of active immunization the author recommends limiting it to Schick positive children and isolating patients undergoing treatment with toxoid. He also recommends isolation of all patients with sore throat who are diphtheria positive, of permanent carriers and of temporary carriers with a positive virulence test.

Book Notices

Food Values in Shares and Weights By Clara Mao Taylor Ph.D., Assistant Professor of Nutrition Teachers College Columbia University, New York Cloth Price \$1.50 Pp 92 with 10 illustrations New York Macmillan Company 1942

Those who are confronted with the task of evaluating the nutritional value of diets will be interested in this useful volume, which replaces the earlier booklet by the author and the late Dr Mary Swartz Rose. The values for the important vitamins and minerals of foods are presented for the first time in terms of weights as well as in terms of the "shares" used in the system of dietary calculations which was introduced by Dr Rose. There are values for about 1,300 different items. The quantity of each item selected is a serving, but the weight of the serving is provided in terms of grams and ounces so that one can readily calculate values for other size portions if necessary. For each food the values are listed for calories, protein, calcium and iron, vitamin A, thiamine, ascorbic acid and riboflavin. Vitamin A is expressed in terms of international units and the other vitamins in terms of milligrams. To illustrate the comprehensive content of the book it may be mentioned that under the general heading of "Pies" there are listed the nutritive values for 36 items, and a footnote provides the dimensions of the pies and also gives the values that should be added for iron and thiamine if enriched flour is used in making the crust. There are 10 items under the general heading of "Potatoes." Under "Salad" are listed the values for 30 different kinds. There are 17 entries under the heading "bread" ranging from bread and butter pudding to bread made from Earle process flour. As an indication of the care with which this set of tables has been compiled, attention may be directed to the fact that a slice of white bread (the dimensions are given) is said to weigh 23 Gm when it is bread that contains some dried skim milk whereas a slice of whole wheat bread is considered to weigh 28 Gm and a slice of white raisin bread 33 Gm. These values are correct. Most compilers of food values seem to be content to consider a slice of bread as one which weighs uniformly 1 ounce, which is far from the actual facts in many instances. It is hardly likely that any ordinary dish has escaped being listed in this compilation of values. The book also provides the recommended daily allowances for specific nutrients. There is also a brief chapter devoted to the graphic presentation of food values. This book will be useful to all those who are concerned with the practical handling of foods from the nutritional point of view.

Sledman's Practical Medical Dictionary Fifteenth revised edition with Etymologic and Orthographic Rules By Stanley Thomas Garber B.S., M.D. Fabrikoid Price \$7.50 with thumb index (without index \$7) Pp 1257 with illustrations Baltimore William Wood & Company 1942

This entire book has been reset for the present edition, there have been many additions, eliminations and corrections. The volume follows closely the previous editions of this work, which have proved so valuable. Special attention has been paid to new terms in the field of the vitamins, biochemistry and chemotherapy, also allergy and hematology. The terminology of bacteria has been revised to conform with the classification by a committee of the Society of American Bacteriologists. New illustrations have been added in considerable numbers. An attempt has been made by the editors to return closely to correct Greek and Latin forms, and what are believed to be the correct forms are the ones used for the attachment of the definitions, for example, the term oophorectomy merely refers the reader to oothecotomy. The word ovariectomy commonly used is also defined under the correct term oothecotomy. Indeed the authors say that even under appendicitis the preferable term scolecoiditis is indicated. In other words they have defined an ideal and persist in it regardless of the fact that such words as appendicitis, once established, are not likely to be removed from the language in favor of the new term, however correct that may be etymologically. The long eponyms are referred to as main titles and are defined under the proper names.

Blood Grouping Technique A Manual for Clinicians Serologists Anthropologists and Students of Legal and Military Medicine By Fritz Schiff M.D. and William C. Boyd Ph.D., Associate Professor of Biochemistry Boston University School of Medicine Boston. With a foreword by Karl Landsteiner. Cloth Price \$5 Pp 248, with 45 illustrations New York Interscience Publishers, Inc. 1942

This book is based on a monograph of the recently deceased senior author (*Die Technik der Blutgruppenuntersuchung*, ed 3, Berlin, Julius Springer, 1932). The German book enjoyed a well deserved popularity. The present manual was brought up to date and considerably enlarged. The reader who is familiar with Boyd's important contributions will recognize his share in the text, especially in the chapters on genetics, on blood stains and on application to anthropology. He deserves credit for the excellent translation. The subject is treated in six chapters, which cover the theory, general technique of blood grouping and application to blood transfusions, to exclusion of paternity, to blood stains and to anthropology. The whole field is adequately covered and clearly presented. A novel method of numbering chapters and their subdivisions, modeled after the decimal system of cataloguing used in libraries looks interesting, but only the future will show its practicality for small volumes such as this one. There is a list of well selected references and a good subject index. The binding and illustrations are satisfactory. There are a few defects in the type especially in the preface. Occasional imperfections of style, like 'if the cells being tested are all right for use' (p 37) or 'such cases have been described by a number of workers including (46 65, 60 93)' do not detract from the value of the book which can be recommended warmly to clinicians, serologists and the other specialists mentioned in the title.

Hughes' Practice of Medicine Revised and Edited by Burgess Gordon, M.D. (Clinical Lectures of Medicine Jefferson Medical College Philadelphia) With sections on Nervous and Mental Diseases By Harold D. Palmer M.D. Professor of Psychiatry Woman's Medical College Philadelphia and on Diseases of the Skin By Vaughn C. Carner M.D. Dermatologist to the Germantown and Frankford Hospitals Philadelphia. Sections on Clinical Methods By Robert Charr M.D. Instructor in Medicine Jefferson Medical College. Articles on Endocrinology By Abraham F. Rakoff M.D. Assistant Demonstrator of Obstetrics Jefferson Medical College. Legal Aspects of Medicine By Louis M. Stevens Esq. Resident Board of Trustees of the Presbyterian Hospital Philadelphia. Sixteenth edition. Cloth Price \$5.75 Pp 791, with 36 illustrations Philadelphia Blakiston Company 1942

This book on the practice of medicine has passed through sixteen editions. The new editor for this edition is Dr Burgess Gordon clinical professor of medicine at Jefferson Medical College Philadelphia, who has enlarged the book to accommodate new material on infections chemotherapy and endocrinology and has deleted empirical methods references, older prescriptions and some illustrations to provide space for the new material. The book is still in handy size and still contains a few illustrations. The primary purpose of the editor is to present in concise form the clinical features and treatment of diseases. The book is designed especially for the convenience of those engaged in the practice of medicine, but it is suitable also for use by medical students.

Contact Lenses By Theo E. Obrig A.B. President Obrig Laboratories Inc. New York City. Cloth Price \$5.50 Pp 470 with illustrations New York Obrig Laboratories Inc. 1942

The growing demand for contact glasses by the public and for the technique of fitting these lenses by the medical profession makes the appearance of this textbook especially propitious. The author has for many years written extensively on this subject and has developed a technique both for making a mold of the human eye and for fabricating a contact glass to conform to a plaster cast of that mold. He has been a pioneer in the development of the molded plastic contact glass as contrasted to stock lenses made of glass.

The first chapter deals with an elementary exposition of the anatomy of the eye and certain biochemical and physiologic data important in the fitting of contact lenses. Indications for the use of contact glasses are exhaustively considered. A simple concise chapter on the optics of contact lenses is included and presented in a manner understandable to the ophthalmologist who may not be so well versed in the mathematical optical principles involved.

The history, development and modern forms of contact glasses are extensively considered, and a review of all the literature contributed in the past many years on this subject is represented.

In complete detail the author presents his technique for taking an impression of the human eye and for making the plaster cast. The technique is excellently illustrated both in material and in actual procedure. There is no description of the technique of making the plastic contact lens itself, since the author has maintained this as a secret process known only to himself and his associates. The procedure for fitting the trial contact glass and methods to alter this are described, as well as the accepted technique of fitting the small Zeiss lenses to attain the optical correction necessary to incorporate in the molded lens.

An important chapter on the various solutions available for use as the fluid lens is included. The modern method of fitting contact lenses leaves little to be desired as far as the physical fit of the lens is concerned, however the greatest present day problem is to find for each patient a fluid most suitable for his personal comfort. The author presents a simple and accurate method for finding this solution. An excellent analysis of the causes for clouding of vision or irritability of the eye is presented. The experimental background to solve this problem has been extensive. It is hoped that future research will make available a more universal fluid that may be used to assure a greater percentage of successful cases.

An interesting chapter on contact lens patents concludes the text. For those interested in this whole problem this chapter presents a wealth of material on various contact lenses of historical interest, nowhere else available to physicians. An extensive bibliography and index conclude the work.

The appearance of this book is most timely, since the demand for contact lenses has become so great as a result of popularization in the lay press. It is regrettable that the author has combined so much that is scientific and basic with such commercial propaganda for his own product. The Obrig lens is not the only all plastic molded contact lens available in this country. The technique of fitting contact lenses on such a large scale as to advocate a rural order practice will only prove a failure in many instances. Even though a mold is taken of the eye and a lens made to fit a plaster cast of that mold perfectly, it does not necessarily follow that that lens will fit the eye itself perfectly. The subsequent modification can best be perfectly accomplished by the optician who has made the lens, and under his direct supervision, since a change in the physical fit may greatly alter the optical correction of the final product.

The Complete Book of Diets for All Ages Including Medical Dietetic Suggestions for 325 Common Ailments By Richard M. Field, M.D. Cloth Price \$2.50 Pp 272 Garden City Doubleday Doran & Co Inc 1942

On the jacket of this volume the author is said to have devoted twenty two years to the study of diet, during which time he has acted as adviser and consultant to 26,000 physicians. For the first time, it is said, information hitherto available only to the members of the medical profession is collected in book form for the general public. The book is not recommended. It fails to take account of recent developments in nutrition and it fails to show how one can obtain from ordinary foods the dietary essentials as recommended by the Food and Nutrition Board of the National Research Council. The author condemns such products as enriched bread and vitamin D milk, which have been approved by the Food and Nutrition Board and the Council on Foods and Nutrition of the American Medical Association. Here are some gleanings from the normal diet which is recommended by the present author for persons 21 to 40 years of age. One must avoid all fruits stewed or baked with sugar or canned in syrup, jams, jellies, cranberries and rhubarb. Melons must be shunned unless eaten with no other food except fruits. Breads and cereals are not to be eaten except those mentioned in a small list of arbitrarily selected items. Dried pea or dried bean soup must not be eaten, despite the fact the nutrition authorities recognize these foods as excellent sources of thiamine

and of iron. Veal, pork, ham, bacon, sausage, smoked, spiced or pickled meats, fat or fried meats, gravies, stews or rich sauces, fried liver, kidney, sweetbreads and warmed over meats must likewise be avoided, but reason isn't given. If you are over 35 years of age and wish to follow the author's advice do not eat old, hard or spiced cheeses or any mackerel, salmon or other pink fleshed fish. Avoid canned fish except occasionally, and all fried fish. One is supposed to avoid any vegetables cooked with fat and especially coarse vegetables such as old carrots, old turnips or beets and dried peas or beans. Instead of desserts such as puddings, pastries, candy, stewed fruits or canned fruits the author recommends fresh raw fruits. The author has a daily schedule for persons in different age groups. Every morning from a quarter to half an hour before breakfast you are expected to eat an orange or grapefruit, but it must be unsweetened. In place of this you can have a cup of unsweetened hot water mixed with the juice of half a lemon. Then you dress and eat one of three suggested breakfasts, none of which seem to be very appetizing. Instructions are given for lunch or dinner meals and there is a list of permitted foods. One is supposed to eat two or more salad vegetables at each meal but meats no oftener than once or twice a week. Practically nothing is said of the importance of milk. It is difficult to understand how any one would be tempted to undertake such a dietary system. This is as it should be, because one could follow the instructions of the author and still fail to secure all the dietary essentials in adequate amounts.

Religion in Illness and Health By Carroll A. Wise. Cloth Price \$2.50 Pp 279 New York & London Harper & Brothers 1942

The author is the Protestant chaplain at the Worcester State Hospital, one of the largest and most progressive of the Massachusetts institutions for the insane. His position as a student of mental illness from the point of view of religion was established following the pioneer work of the Rev. Dr. Anton T. Boisen in the same hospital. Slowly the need for expansion outside the hospital became evident and a council for clinical training was incorporated, now the basis for teaching the care of the sick to theological students. The instruction is given in many general hospitals as well as in hospitals for the insane, but Worcester, as the pioneer center, holds an important place in the field of mental disease. It is felt by many, moreover, that psychiatric illness offers the most valuable training ground for the junior clergyman and on that assumption the author has written his text broadly covering the subject.

The book is remarkably complete and shows wide reading by the author. The first hundred pages covers the subject of psychosomatic psychiatry, each chapter giving references to the latest literature. The author has been much influenced by the researches of Flanders Dunbar and Walter B. Cannon, but his reading has been by no means confined to these fundamental contributors to psychologic medicine. There is perhaps, from the point of view of medicine, a slight lack of discrimination in references and failure of evaluation, but in general there is little to criticize except on the side of redundancy. Careful editing could have reduced the volume of these chapters considerably.

The last two thirds of the book deals with religion in its relation to illness, particularly mental disease as viewed by a man of discerning mind who has had a long experience in association with psychiatry. The sections on abnormal psychology are of the most importance to the physician, particularly those on religious symbols. He makes no new contributions to the subject, but his setting forth of this difficult material is good.

The book is directed to the theological student and, from the point of view of medicine, it may be considered as a well written, essentially sound book. It should be endorsed by the medical profession and used to encourage the further expansion of this field of endeavor, both in general and in mental hospitals. For the clergyman attached to a general hospital, a book one third the size of this one, with the omission of some of the less well established theories of psychosomatic medicine, would fill an urgent need more admirably than this larger text.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CLINICAL TUBERCULOSIS AND CALCIUM DEPOSITS IN PULMONARY PARENCHYMA

To the Editor—About ten years ago I had a roentgenogram taken of my chest which revealed about twenty calcified tubercles throughout the pulmonary parenchyma which ranged in size from 0.1 cm to 0.4 cm. Recently I was called up for examination for the army and was rejected on the basis of the findings of a similar roentgenogram. Regulations demand rejection of individuals who show more than ten such lesions. What is the probability of recurrence and what is the basis for choosing ten lesions as the maximum? I never suspected that I had tuberculosis for there is no history of contact. M D Ohio

ANSWER—The finding of twenty calcium deposits in the pulmonary parenchyma is of itself not sufficient evidence to justify a diagnosis of tuberculosis. Unfortunately, when densities are seen on x-ray films of the chest, which are thought to represent deposits of calcium, they are all too often reported as representing tuberculosis of the primary or first infection type. All one visualizes in this manner is a shadow, and the lesion in which the calcium or bone is deposited is microscopic. The etiology of such conditions is nearly always microscopic and therefore one cannot hope to determine etiology by a microscopic method limited only to the inspection of a shadow.

The fact that there is no known exposure to contagious cases of tuberculosis is not significant, since there are numerous carriers of tubercle bacilli who are unaware of the fact that they are spreading the disease. Indeed, approximately 50 per cent of the patients with clinical tuberculosis in hospitals and sanatoriums do not know when or where they were exposed to the disease.

In an examination for tuberculosis, the physician has only two specific findings. One is the recovery of tubercle bacilli from the suspected lesion, and the other is the tuberculin reaction due to the sensitivity of the tissues to tuberculinoprotein. Without one or both of these, no one can possibly make a diagnosis of tuberculosis.

Olson and his co-workers have recently stated that "the finding of pulmonary calcification, particularly in tuberculin negative individuals should not be assumed to be evidence of infection with tuberculosis." Symptoms, physical signs and x-ray findings are not specific; they may be identical in several different diseases, regardless of whether it is a matter of deposits of calcium, infiltration, consolidation or even cavitation.

If the tuberculin test is administered and the inquirer is a nonreactor, it is excellent evidence that the lesions are not tuberculous or at any rate that they do not harbor living tubercle bacilli. The fact has been well established that tubercle bacilli may die in the lesions of primary complexes, after which the sensitivity of the tissues wanes and finally disappears. If the inquirer is a reactor to tuberculin there is still the possibility that the calcifications are due to a nontuberculous condition, since persons infected with tubercle bacilli are as likely to develop nontuberculous disease as the uninfected. However, if the inquirer does react to tuberculin there are undoubtedly primary tuberculous lesions in the body and there is a good possibility that some of them are in the vicinity of the calcium deposits. If it is proved that the lesions were produced by tubercle bacilli, they probably represent only primary foci. Primary tuberculosis complexes are usually multiple; in fact it is hardly conceivable that an individual could become infected with a single tubercle bacillus. When many bacilli enter the body, it is most unlikely that all of them could be ingested by a single neutrophil, and, when many neutrophils participate in the ingestion of tubercle bacilli, one could hardly expect circumstances to be such that they would all focalize at the same point in the body. Indeed, the neutrophils containing tubercle bacilli may lodge at various places, some in the brain, some in the liver, others in the kidneys, lungs and elsewhere. Wherever such neutrophils lodge there is the likelihood that a tubercle will result and the regional lymph nodes become involved and, thus, a primary complex is formed. The fact that one sees no evidence of such a complex on the x-ray film does not constitute the slightest proof that they are not present. When one obtains some evidence on the x-ray film of a deposit of calcium in the lung, one is cognizant of the fact that many other such complexes may be present in the same lung but are so located or

of such minute size that their shadows are not visualized by naked eye inspection.

Therefore there is no scientific reason for excluding an individual from any activity in life because of any given number of calcium deposits on an x-ray film. If the calcified lesions are tuberculous, there is considerable doubt whether the inquirer is more likely to develop clinical tuberculosis at some subsequent time than another person who reacts to tuberculin and has no x-ray evidence of calcifications in the lung. The majority of the persons who develop primary tuberculosis complexes and thus become tuberculin reactors live out the span of life without significant illness from clinical tuberculosis. There is a significant minority, however, who do develop this type of disease; indeed, it is in this minority that occur all the cases of serious illness. Since there is no way to determine whether the tuberculin reactor, with or without evidence of calcium deposits revealed by x-ray film inspection, belongs to the majority or minority group the only safe procedure is to have examinations at least annually.

THE NURSE AND THE ADMINISTRATION OF ANESTHETICS

To the Editor—I am writing to inquire concerning the accepted status of graduate nurses employed by an approved hospital in connection with the administration of preoperative avertin with amylene hydrate. It is of course recognized that the general condition of the patient and the blood pressure should be known to both the anesthetist and the surgeon. Under these conditions I should like to ask the following questions: If the weight of the patient is reported to the anesthetist by the nurse is it entirely outside the domain of the operating room nurse (who has been thoroughly instructed regarding the preparation of avertin with amylene hydrate) to administer this with the dose calculated by the anesthetist or is it the duty of the physician to administer the drug himself? Also after the administration of the drug is it a recognized duty of the anesthetist to remain at the patient's bedside for the twenty or thirty minutes prior to being transferred to the operating room or may this responsibility be rightly detailed to a graduate or senior nurse? Our medication with avertin with amylene hydrate has always been in the lower dosage scales and no difficulty has been experienced to my knowledge in some six or eight years of rather widespread use. However we are making a special effort to conform to generally accepted procedures. M D Ohio

ANSWER—It is difficult to draw a line of demarcation between technical and professional services in a modern hospital. If the physician can train a nurse or nonmedical person to perform satisfactorily certain procedures at the direction of the physician and for the results of which the physician holds himself directly responsible, no harm to the patient need result. This attitude may be justified concerning some of the procedures involved in drug administration for the relief of pain. The consciousness of the physician in holding himself responsible for the action of his agent is the important element in such relationships. In the circumstances cited in the question, if the physician who acts as anesthetist makes himself familiar with the condition of the patient and orders a dose of avertin with amylene hydrate, he may be within the bounds of safe practice. That will depend on whether he has developed a plan of anesthesia for that particular patient. It should be based on the physical findings, the demands of the surgical procedure and the drugs and methods which he proposes to use to complete the anesthesia.

The danger to the patient after the administration of avertin in amylene hydrate is roughly dependent on the promptness with which respiratory obstruction or depression is recognized and the promptness with which proper treatment is instituted. Whether the nurse may safely supervise the welfare of a patient for thirty minutes after the administration of avertin in amylene hydrate will depend on whether she is trained in the quick application of artificial airways and artificial respiration and whether she can receive the prompt assistance of the physician if trouble develops.

VITAMIN B₁ IN MIGRAINE

To the Editor—Will you kindly give me reference to the use of vitamin B₁ in large doses for migraine headaches, also your opinion regarding its use. Frank H. Boone M.D. Hamilton Canada

ANSWER—The use of vitamin B₁ in the treatment of migraine has been described by H. D. Palmer (Treatment of Migraine with Vitamin B₁. Resume of One Year's Experience, *Arch Neurol & Psychiat* 45:368 [Feb.] 1941). Dr. Palmer has other references which may be obtained by writing him at the Institute of Pennsylvania Hospital, 110 North Forty-Ninth Street Philadelphia. The trial of this vitamin together with the entire B complex seems warranted in many cases of migraine. It is not as yet certain how effective it is in typical migraine.

ROLLINS AND THE ABORTION OF COLD BY X RAYS

To the Editor—For some time I have been gathering data for an article on Dr. William Rollins of Boston, an early worker in radiography. In the May 27, 1897 issue of the *Boston Medical and Surgical Journal* he published the following communication to the editor: "Boston May 10 1897 Mr Editor—Since Roentgen's discovery, I have been free from what is commonly called a cold. My profession exposes me constantly to contagion of this kind for I operate at least every two or three days on the teeth of patients suffering from this disease. As I formerly suffered severely in this way I attribute my present immunity to the fact that whenever I feel a cold beginning I start one of my generators and keep it running taking the further precaution, when I have a few moments time to shut myself in a room with all the generators that happen to be in operative condition. As I feel quite sure there is some remedial action from these machines, I should like to see the air of hospitals charged in this way. Yours truly William Rollins." Has there ever been any experimental work done to prove or disprove Dr. Rollins' theory?

A. Porter S. Sweet D.D.S., Rochester, N. Y.

ANSWER—Dr. Rollins himself in note 122 page 174, in his "Notes on X Light" seems in 1901 to disagree somewhat with his observation of 1897. Under the title "Removing the Irritating Gases Produced by X Light Generators" he says: "A powerful x light generator produces ozone and combinations of nitrogen and oxygen. These are irritating to the respiratory mucous membranes. A fan should be placed within the case of a static machine to drive the gases into the nearest chimney. A coil should have the sparks gaps enclosed, the gases being drawn by an aspirator into the waste water pipes."

Since this date much attention has been paid to the principle of ozonization in air purification and to the method of recovering nitrogen from the air by high voltage electrical discharges. It one now assumes a beneficial action of ozone on the impurities of the air and assumes an irritative action of various nitrous oxides on mucous membranes the question at once arises as to whether the commercial 'ozonator' uses such electrical voltage as to break up the oxygen without at the same time breaking up the nitrogen of the air. The effectiveness of x rays in aborting a cold is not certain.

SUDDEN INJURY AND THROMBOSED HEMORRHOID

To the Editor—A man aged 60 was working in his shop carrying a heavy load. He slipped but caught himself and did not fall. Immediately he felt pain in his rectum and a small tumor appeared which during the remainder of the day grew in size and caused him increasing pain. Two days after the accident the patient presented himself to me and a cherry sized thrombosed hemorrhoid was noted. Under conservative treatment the condition was well controlled and no trace of it remains at this time. The patient is a trustworthy person and he assured me that he never suffered from hemorrhoids and that at no time had he had any experience like the one described. Please advise whether in your opinion an accident could be a competent cause to affect a thrombosed hemorrhoid. Are these cases covered by workmen's compensation?

M.D. New York

ANSWER—A sudden rise in venous pressure, which may occur under the circumstances described, may well be related to the appearance of a thrombosed hemorrhoid. To establish an undisputed connection with the injury, however, the man would have to show that a previous rectal examination revealed no hemorrhoids, as the statement that he had no preexisting symptoms does not rule out hemorrhoids nor does it eliminate the existence of pelvic and, especially, periprostatic thromboses, which are not infrequent in men of his age. Even so, an aggravation of a preexistent lesion might be argued. As long as complete functional recovery ensued, presumably within a short time, the question is rather of an academic nature. If the man had developed a rectal abscess or embolic phenomena, his long lasting disability or possibly death by pulmonary embolism would require a careful weighing of medical evidence during which much could be said for and against compensability on the basis of the man's vascular status.

See Brahm, Leopold, and Kahn, Samuel. *Trauma and Disease*, ed 2, Philadelphia, Lea & Febiger 1941.

TEMPERATURE OF WATER NECESSARY TO PRODUCE BURN

To the Editor—Can you tell me approximately what temperature water must be to cause a second degree burn in an adult with particular reference to a short exposure such as would be experienced in a shower bath?

M.D. Roanoke Va

ANSWER—In animal experiments to produce a third degree burn it requires approximately a temperature of water of 70 C (158 F) with a ten second exposure. It is estimated that a temperature of 55 to 65 C (131 to 149 F) might produce a second degree burn. The skin of adults varies so there could be no constant figure as regards the temperature of water other than as mentioned.

GOAT'S MILK

To the Editor—The classified directory for Birmingham Ala contains the following statement: "The Journal of the American Medical Society states: 'The goat is the healthiest domestic animal known. Goat milk is superior in every way to cow's milk. Goat milk is the ideal food for babies convalescents and invalids especially those with weakened digestive powers. Goat milk is the purest, most healthful and most complete food known. Is this an authentic quotation and a true statement of fact?'"

M.D. Alabama

ANSWER—Original articles, editorials, Queries and Minor Notes and correspondence mentioning goat's milk which have appeared in *THE JOURNAL* have been examined to see whether this statement appears. It has not been found. There was a letter written to *THE JOURNAL* by William L. Secor M.D. Kerrville, Texas published in *THE JOURNAL* for March 3, 1923, which stated: "We can recommend goat's milk to our patients as far superior to cow's milk chemically, physically and bacteriologically," when brucellosis in goats is better controlled. The alleged value of goat's milk in diabetes was discussed in *QUERIES AND MINOR NOTES* in *THE JOURNAL*, May 27, 1939, page 2193. The Council on Foods and Nutrition has accepted two goat's milk products which are recognized as useful in the feeding of infants who are allergic to cow's milk. It would appear that goat's milk is similar chemically to cow's milk and as a general purpose food probably is in no way superior. Like cow's milk goat's milk is known to be deficient in iron and is a negligible source of vitamin C.

AMPHETAMINE INHALATION AFTER CORONARY OCCLUSION

To the Editor—About eight months ago I had a mild coronary occlusion practically without symptoms but definite in the cardiogram. I was in the hospital for seven weeks and have observed the usual precautions since. Up to the attack I had on occasion used the amphetamine inhaler for coryza usually with a great deal of satisfaction and relief. Since the attack I have hesitated to use this remedy as I am not sure of its action on the heart. I have not needed any medicine for some months but it would seem illogical to take a dilator for the cardiac vessels and then use a constrictor in the nose provided the action reaches the heart. I have no literature that covers the point in question and am not able to travel far in search of it hence the appeal to you. If this information is available I will value it highly.

M.D. California

ANSWER—Amphetamine inhalation does not have any important effect on the heart or coronary circulation, at least in the absence of a high degree of coronary insufficiency. When there is a well healed myocardial infarct, as probably exists in the case of inquirer, there should be no hesitation in resuming the amphetamine inhalations for coryza. The observations of three consultants who have had extensive experience in allergy, nose and throat work and cardiovascular disease have not uncovered any instance of any important or serious effect of amphetamine on the heart.

TEMPORARY HEARING IMPROVEMENT IN DEAFNESS

To the Editor—I have had a chronic otitis media (left) for many years. I am 55 years of age. In 1932 following a case of flu the hearing in my right ear suddenly became greatly diminished. This had happened two or three times before during that same year but not before 1932 each time following a cold or flu when I recovered from the illness my hearing would return to normal in the right ear. My hearing in the left ear has been poor since I can remember. In 1936 audiometer tests showed that hearing in both ears was between 40 and 50 per cent. I do not remember exactly. I think that I have experienced an unusual phenomenon in that several times since 1932 I have had the following experience. When I have a cold or flu (and I have been subject to them often) during some of the attacks I have been able to hear the small clock tick on my desk. Ordinarily I must hold it against my ear to hear it at all. At these times I would hear it and wonder what it was and then realize that it was the clock from which I would be at a distance of 3 to 4 feet. Maybe I could hear it for several hours. And when I would stroke my unshaven face there would be the old loud roaring or scraping sound as of yore. Soon, within a few hours my hearing would become poor again and remain that way until I contracted another cold. Is there any explanation for this phenomenon? Does it mean that some form of treatment would be of value?

S. Ross Jones M.D., Corpus Christi Texas

ANSWER—Occasionally in cases of chronic adhesive deafness such as appears to exist here the hearing will be temporarily improved by various occurrences. The explanation for these fluctuations is not always clear but there are two possible mechanisms: (a) temporary occlusion of the eustachian tube and (b) presence of moisture, cerumen or other substance in the middle ear against the oval or round window acting as a prosthesis to increase the conduction of sound to the inner ear. A diagnostic catheter inflation of the eustachian tube and the use of a prosthesis such as a pellet of cotton moistened with glycerin might help to determine which if either mechanism is operating.

BROKEN NEEDLE IN DELTOID

To the Editor—On Jan 19 1942 while I was injecting theelin into the deltoid muscle of a patient's left arm the hypodermic needle, which was a 25 gage, 5/8 inch length needle (B D Erusto) broke off in the patient's arm. On the same day roentgenograms were taken and an unsuccessful attempt to remove the fragment under the fluoroscope was made. An incision was made over the site of the needle and closed with dermal suture. Healing has progressed normally and there has been no pain nor untoward symptoms. No further attempt has been made to remove the needle fragment which is 5/8 inch long. What is advisability of taking further roentgenograms at the present time and making another attempt at removal? What are the dangers from leaving the needle fragment in the arm? What is the best procedure to follow for removing the fragment at this time if it is necessary to remove it?

M D, Indiana

ANSWER—Since the needle is not causing symptoms, it is wise to leave it alone. A fragment of metal in this location is not apt to produce subsequent trouble. If however, it becomes necessary to remove it, roentgenograms taken in planes at right angles will help in localization. Dissection is facilitated if done with local anesthesia and the field well infiltrated with procaine hydrochloride to which epinephrine is added to secure vasoconstriction.

TISSUE EXTRACTS AND CIRCULATION

To the Editor—Can you refer me to any literature on the use of heart extract in the treatment of paroxysmal tachycardia or other conditions?

Willis P. Baker M.D. Santa Ana Calif

ANSWER—In the past five years little has appeared in the English or American literature relative to the use of heart and other tissue extracts. Indeed, the foreign language literature contains much less material of this nature than formerly appeared. Some years ago a number of these substances were investigated. The common ones were kallikrein or pralutin, insulin free pancreatic extract, muscle adenosine phosphatase, locarnol and myostan. These substances were used primarily to increase the blood supply both in the coronary and in the peripheral circulation. A fairly comprehensive reference bibliography may be obtained from the following publications:

Elliot A. H. and Nuzman F. R. Urinary Excretion of Depressor Substance (Kallikrein of Frey and Kraut) in Arterial Hypertension. *Ludocermology* 18:462 (July-Aug.) 1934.
Barker N. W., Brown G. E. and Roth G. M. Effect of Tissue Extracts on Muscle Pains of Ischemic Origin (Intermittent Claudication). *Am. J. M. Sc.* 189:36 (Jan.) 1935.

ELECTROCOAGULATION FOR EXCESSIVE HAIR

To the Editor—Recently I have read in the Encyclopedia of Surgery and Modern Medicine of the removal of superfluous hairs by the short wave diathermy as well as by the electrolytic process using galvanic current. Is the short wave method just as good? What is the removal process using the short wave diathermy?

R. Henry Temple M.D. Kinston N.C.

ANSWER—While electrolysis is the common, safe method in use for the removal of superfluous hair, the electrocoagulation method has its advocates, and a complete discussion of this method of treatment for hypertrichosis may be found in the *Archives of Dermatology and Syphilology* (45:228 [Jan.] 1942). Treatment with either method is painstaking and slow, and in the discussion mentioned several of the advocates of the electrocoagulation method discuss their experiences with it and its method of employment.

MIGRAINE ASSOCIATED WITH MENSTRUATION

To the Editor—A woman aged 45 has had at each regular menstrual period since the birth of her only child sixteen years ago, attacks of migrainous headache. These are accompanied by vomiting and some dizziness. Occasionally she may go through the menses without symptoms. I have given her estrogenic substance as high as 50,000 units twice weekly and no results although for the first few months after beginning treatment she had much diminution of her symptoms but lately they have again recurred severely. I have also tried vitamin B₆ to no avail, also thyroid. There is no anatomic or physiologic abnormality in the pelvis.

G. E. Michell M.D. Hocketsstown N.J.

ANSWER—The patient has the type of migraine (hemiergia) that is associated with the menses. Migraine is a protan disorder and may be a simple or an extremely complex condition. The present concept is that the periodic headaches are due to a vasomotor disturbance. Nothing positive is known regarding the active cause. This type of headache usually disappears during pregnancy and after the climacteric. Estrogens and vitamin B₆ are almost always ineffective. Rest, proper bowel hygiene, abstinence from alcoholic beverages and some sedative are cardinal points in the management of the usual case. In this instance the patient may be given either sodium bromide or fluidextract of cannabis three days before the onset of the

menstrual period, continued daily until three days after the menstrual period. The dose of sodium bromide is 1 Gm. (15 grains) three times daily. The dose of the fluidextract of cannabis is five drops three times daily, increased daily by one drop until eleven drops, three times daily, are taken. Then the dosage is reduced by one drop daily until five drops are taken three times daily and so on. In a few cases ligating the middle meningeal artery on the affected side has been tried. This procedure is not without danger and is not recommended. Ergotamine tartrate may also be used.

INTRADERMAL TESTS AND UNSTERILIZED NEEDLES

To the Editor—Would you please let me know if there are any objections to using the same needle without sterilization between injections in doing a series of Mantoux tests? If for instance, one person has syphilis is there any danger of transferring the disease to the person next in line without previous sterilization of the needle? The argument put up by one physician is that since the needle is introduced intradermally, without contact with blood there is no danger of transference. I do not think however, that I should like to have a boy of mine next in line. I should be obliged if you would settle the question for me.

M.D. Washington

ANSWER—The argument that a needle introduced intradermally does not come in contact with blood is not valid, because it is practically impossible to make such injections entirely intradermally. Aside from the possibility of transferring spirochetes, however remote that might be, other organisms are present in the skin which might be transferred from one individual to another. Although the danger of such transference may be slight, intradermal tests should not be performed so routinely that individually sterilized needles could not be used.

TRICHINOSIS IN PREGNANCY

To the Editor—A woman aged 30 is four months pregnant and has on acute trichinosis. I do not know the relationship of trichinosis to pregnancy and vice versa for I could not find anything about it in books. Logically I see the mother's life endangered twice: trichinosis and with trichinosis the pregnancy. Calcium is needed for the encapsulation of the *Trichinella spiralis* embryos and on the other hand calcium is needed for the fetus. Which will take the calcium? I should be glad to receive information of what can happen and what should be done in this case.

Heinrich Kuerer M.D. New York

ANSWER—Available data indicate that trichinosis bears the same relationship to the pregnant patient as to the nonpregnant. The investigations of Stiehl and those of Augustine revealed that a prenatal trichinosis infection does not occur in the lower animals or human beings. Since there is no specific therapy for trichinosis, treatment of a pregnant patient should be of the usual supportive type. As far as is known, calcium required for the encapsulation of the trichinae does not demonstrably disturb the calcium metabolism of the host. It is not likely that either the mother or the fetus will suffer from a calcium deficiency if the normal requirements of calcium intake for pregnancy are satisfied.

SILICOSIS AND THE HEART

To the Editor—A patient has silicosis as proved by x-ray examination. The symptoms are coughing, shortness of breath, dyspnea and swelling of the feet and ankles. I should like to know if silicosis affects the heart and if so how?

John Repasky M.D. Akron Ohio

ANSWER—There is no proof that simple, discrete silicotic nodulation has any effect on the right side of the heart. Patients with conglomerate reaction in the lungs often due to associated infection are more apt to exhibit cardiac symptoms. In the latter instance, compensatory emphysema and chronic adhesive pleurisy tend to accentuate the effect of the obstructive lesion on the pulmonary circulation. However, it is difficult to prove that even conglomerate silicosis is a primary cause of cor pulmonale. Most cases occur in persons over 50 when essential disease of the cardiovascular system is common. The massive fibrosis of the lungs may then aggravate the cardiac symptoms.

AMINO ACIDS AND BRAIN TUMOR

To the Editor—The husband of a former patient of mine who had a brain tumor removed in July 1936 says in a recent letter that she is suffering again. He enclosed a clipping which I am transmitting to you regarding the effects of amino acids. I am wondering if they are doing any good.

E. J. Emerick M.D. Columbus Ohio

ANSWER—There has been no presentation of scientific work done on the effect of mixtures of amino acids on brain tumors before any of the national societies of neurologic surgery or neurology. It is possible that it is being investigated, but the results have not yet been made available to scientific bodies.

POSTGRADUATE EDUCATION IN OTOLARYNGOLOGY

CHAIRMAN'S ADDRESS

GORDON F. HARKNESS, MD
DAVENPORT, IOWA

As of Feb. 3, 1942, there were about 180,700 physicians in the United States. The approximate subdivision of this number is given in table 1.

With the exception of a small minority, the medical profession has advocated individualism in the application of its science. The progress of medical science and education in this country is cited as justification for the continuance of the present basic type of medical practice.

Specialization in different fields has come as a natural consequence and with it greater emphasis on postgraduate education. During the adolescent years of the special fields of practice in medicine, there was a great lack of educational facilities. Present-day criticism of the former, all too superficial courses, many operated without supervision for personal profit, forgets that they were a part of the defects of the general medical educational program prior to present-day standards. Yet out of this earlier system, there were developed men of outstanding ability. What is often forgotten is that one's education in medicine is never finished. Countless examples can be offered showing that the individual who follows this axiom will eventually prove himself to be superior to those who have had greater opportunities for preliminary preparation but have failed to carry on.

There is an economic side which medical education should recognize that has to do with those delivering medical service. Whether four years' premedical college education is the optimum is a question. Not all educators are agreed that from a cultural or later efficiency standpoint it should be required. The fact that those entering medicine with a college degree show an average higher scholastic rating does not entirely answer the question. The average age of the medical graduate at the present time is 26. With an additional one year's internship required, the question of then entering practice or preparing for a limited field of medical activity confronts him. One year's hospital service is the minimum and certainly two years is much preferable if one is adopting a special field, for basically we are or should remain doctors of medicine. Granting

that three years of training in a special field of medicine is desirable, this brings the average age to 31 before entering private practice. In private practice, it will take from eight to ten years before the average man will reap an adequate reward for his efforts, and in fifteen to seventeen years he will attain his maximum or peak, which he can expect to retain from ten to twelve years, when a period of decline can be anticipated. In other words, at about the age of 40, he should be having adequate compensation for his labors. By 46, he reaches his peak, and by 56, the period of decline can be expected. He has been his own invested capital, and when this period of decline comes, there is no chairmanship of a board to which he can retire and be compensated. I mention this only to preface what the commonwealth actually needs in the way of specialized services and how finely we should subdivide the preparation so that such services can be rendered efficiently and economically.

We have had a sister specialized field, ophthalmology. Few of the older men still practicing did not embrace both fields earlier in their careers. After they gravitated to one or the other, they were better men for having at one time applied their knowledge to both. There is something to be said against narrowing one's horizon too much. This may be debatable, but there is an economic side that is not to be disputed. There are communities which are entitled to good service but are not large enough to support physicians devoting their attention only to ophthalmology or otolaryngology. Statistical studies are lacking, but the American Board of Otolaryngology, some four years ago, put out a questionnaire which the secretary, Dr. W. P. Wherry, informs me warrants the conclusions that

A city to support a good ophthalmologist or otolaryngologist limiting his practice to one of these two specialties should have at least 35,000 to 50,000 population.

A city of 25,000 could support one or two good combined eye, ear, nose and throat men.

Cities of less than 15,000, particularly if located close to large centers, would have difficulty in maintaining more than one good combined specialty.

A glance at our population centers will show the necessity of service to smaller population groups. The division of our population according to the 1930 census is given in table 2.

From figures available, there are 51,026 physicians in this country professing to limit their practice to special fields, with approximately 20 per cent more giving special attention to these fields. Statistical information from the Bureau of Medical Economics of the American Medical Association reveals that there

are 1,435 limiting their work to ophthalmology, 1,674 limiting their work to otolaryngology and 4,358 limiting their work to ophthalmology, otology, laryngology and rhinology. Some 20 per cent more give special attention to these fields.

According to the report of the Council on Medical Education and Hospitals revised to September 1941

TABLE 1—*Distribution of Physicians*

Classification	Number
Not in practice or retired	8,700
Interns residents or others in hospital service	18,000
Government service (Regular Army Navy U S P H S Administration and Indian Service)	5,000
Medical Reserve Corps (Army Navy and National Guard) on active duty	11,000
Employed insurance companies teaching public health industrial firms laboratory work not in private practice	4,400
	49,700
Those in private practice	132,000
	180,700

relative to approved institutions for residencies, length of service, number of residencies and assistant residencies, I have obtained the data presented in table 3. The average annual admittance is rather difficult to state from the report but is estimated as given.

The length of service varies from one to six years (table 4). The one year services are offered in about one third of the institutions, and this same proportion exists in those institutions offering a combined service. The impression gained as one attempts to digest these figures is the lack of correlation of these services to the needs of the country. One year is too short a time for proper preparation for one intending to limit oneself to ophthalmology or otolaryngology, six years would be too long for one to spend preparing for a combination of ophthalmology and otolaryngology. It would seem that most of our outstanding institutions prefer to carry out this postgraduate education independently in their departments of ophthalmology and otolaryngology. One wonders whether greater correlation of effort for those who will not in practice separate the two might

TABLE 2—*Division of Population*

	No. of Cities
Communities of 1,000,000 and over	5
Communities of 500,000-1,000,000	8
Communities of 250,000-500,000	24
Communities of 100,000-250,000	56
Communities of 50,000-100,000	98
Communities of 25,000-50,000	180
Communities of 10,000-25,000	606
Communities of 5,000-10,000	861
Communities of 2,500-5,000	1,332
Communities under 1,000-2,500	13,433

yield more practical results. These remarks are in no sense belittling the most thorough preparation for the man who decides to limit himself to but one of the two specialties but are intended rather to emphasize the practical needs of medical service in the specialties as it is and will continue to be delivered. The smaller communities are entitled to good medical service, including the specialties. The efforts of our best institutions should be lent to further this cause as well as prepare men who choose to limit their activities further in metropolitan centers. As one who has lived his pro-

fessional life on the firing line of private practice, not in the smaller but also not in metropolitan centers, it has seemed that if the basic special training is too finely divided there will result inability to distribute the products of this training to the best interests of the public, together with fair compensatory rewards to those delivering the service. It is equally important that there should be inculcated in the minds of medical men, for the best interests of the public, the fact that the best application of scientific medicine today endorses not only special fields of practice but special fields within special fields. The most successful relief of many conditions requires constant practice of dexterity and properly trained assistance in professional and hospital personnel. It is no reflection on intellectual capabilities but rather to the credit of the man who recognizes the need of the patient for the specialist within the specialty and, in the interest of better service, refers him to one whose environment gives him the opportunity to deliver it. Smaller communities are entitled to this service, but it cannot be accomplished by too fine a limitation of activities. I can point to communities into which have gone men particularly well trained in one or the other of our related specialties but because of local or economic conditions have then embraced and practiced the sister specialty with practically no preparation surely an inconsistency of precept. Believing firmly in the benefits of competition I would even venture the

opinion that, in a community large enough to support one ophthalmologist and one otolaryngologist if they alone occupied the field, the community would not get as good service as if it had two competing men who embraced both fields. The smaller communities are entitled to the services of well trained men, men whose intellectual capabilities are on a par with those whose field of activity may be more limited. These communities should have men who possess the diagnostic ability to advise patients properly even though their opportunities prevent them from rendering every service. To supply this type of trained men should be part of the program of postgraduate education of our best institutions.

The success of the various self-appointed examining boards has demonstrated, by the cooperation of men already successfully established a desire to establish standards for improvement of service and protection of the public. The basic purpose of these boards is not to establish the ultimate ability of each authenticated candidate. They cannot be responsible for his professional morality. They serve their purpose when they can state that, after careful investigation and after a fair examination, it is their belief that the certified physician is a safe man to practice his particular field of medicine. To subdivide too finely, to look askance at the man who because of environment does not quite conform to what might be expected in a different population center, will hinder rather than advance a program of greatest merit. Speaking as one who has had the

opportunity of observing the marvelous advances of undergraduate and postgraduate medical education for nearly four decades and the recognition of special fields of activity with self-imposed standards of requirement one can well pay homage to those who have accomplished all this. It has, however, complicated the picture. Better medicine has meant more expensive medical care and with it more economic problems. This potpourri of economics, scientific medicine and population groups means that our long range educational program to supply medical service must be practical for all population groups—that too fine and restricted a subdivision of recognized fields of service may hinder rather than advance the program. We shall be judged by the service that is rendered as a whole and not by the accomplishments of any one individual. Utopian

Recreation a Sovereign Remedy—England in her urgent haste and out of her harrowing experiences has learned the healing and restoring power of recreation, not only for men in the service and little children terrified by the commotion but for even the most elderly and prosaic. The treatment of physically ill patients by prescribed recreation is a common sense procedure utilized by many physicians without any scientific authority or guidance. Many a man is told to let up on some of his business activities and take a trip who hasn't the slightest capacity for utilizing such a trip for anything but the enhancement of his misery. Many a man is told to play golf who is not only unfitted for golf but who doesn't like golf and who whacks at the ball and tramps his weary rounds on the golf course in the same spirit that he downs a teaspoonful of elixir of quinine. On the other hand, properly adapted to the individual there is no question that recreation can be and has been a sovereign remedy.—Menninger, Karl, and Menninger, Jeanetta Lyle. *Recreation for Morale*, *Bull Menninger Clin* 6:96 (May) 1942.

CONGENITAL FLATFOOT

JOHN G. KUHN'S, M.D.

BOSTON

Weakness and other disturbances of the feet are found in more than 50 per cent of all small children.¹ Many of these disturbances disappear spontaneously as the child develops better balance and skill in walking. But a small number, about 0.5 per cent, will show persisting ligamentous relaxation of the feet with displacement of the medial tarsal bones inward and downward on weight bearing. Without adequate treatment these feet, showing extreme relaxation, progress to much functional disturbance in adult life. At birth the deformity of the feet in this group varies in severity from simple ligamentous relaxation to fixation of the foot in calcaneovalgus. Much confusion exists in medical literature about these feet because different writers have described different degrees of this deformity.

The patients with milder deformity often show generalized relaxation of the subcutaneous tissue and of ligamentous structures—the so-called Ehlers-Danlos syndrome.² The more severe ones frequently resemble the pes calcaneovalgus congenitus described in the older medical literature.³ Seen in adolescence, many of these feet show subluxation of various tarsal bones and increasing deformities of the bones of the feet. From a study of feet of children during the past ten years, with prolonged and discouraging attempts at correction, we feel that this group, with its many variations can best be called congenital flatfoot. At birth all show unusual ligamentous relaxation.⁴ In all of them the midtarsus is displaced inward and downward on weight bearing, with depression of the longitudinal arch. Treatment is tedious and improvement is slow. All progress to serious disability if the condition is not treated.

In infancy and early childhood congenital flatfoot can be diagnosed primarily by the extreme ligamentous relaxation about the foot. The dorsum of the foot can frequently be brought to the anterior surface of the tibia⁵ (fig. 1). Passive, painless subluxation at the tarsal joints often occurs. In the more severe deformity the foot may be constantly in eversion and dorsiflexion. Usually it can be brought into inversion passively without difficulty. Examination of the depression of the arch on weight bearing is usually of no assistance before the age of 2 years.⁶ When the child begins to stand extreme valgus of the foot is found with inward and downward displacement of the astragalus and scaphoid (figs. 2 and 3). Walking by these children is often delayed. There is defective balance and great awkwardness, and the shoes become misshapen rapidly.

Roentgenograms are of little assistance in infancy since only three or four osseous centers are visible.

Later a number of changes are seen. The development of the osseous centers of the tarsal bones and the appearance of the epiphyses are often delayed⁷ (fig 4). After the age of 6 years deformities in the tarsal bones and subluxations are found in a large number of congenitally flat feet. The astragalar neck is frequently

Fig 1—Congenital flatfoot excessive relaxation of the foot particularly the achilles tendon

elongated and twisted externally in relation to the body. The articular surface between the astragalus and the os calcis in weight bearing becomes parallel to the ground, and this may lead to permanent deformity at this joint. There may be anterior displacement of the external malleolus. The scaphoid bone is frequently displaced downward as much as $\frac{1}{2}$ inch from its normal articulation with the astragalus⁸ (fig 5). In adolescence the scaphoid may become wedge shaped with its widest portion on the inner side. The internal cuneiform may become elongated and rounded at its mesial side. Some of these osseous changes in the tarsal bones may be congenital but anatomic studies on fetuses have failed to demonstrate them. It is my opinion that they are chiefly developmental, the result of faulty weight bearing on an extremely relaxed foot.

Fig 2—A congenital flatfoot with downward and inward displacement B congenital flatfoot corrected by insoles and a raise on the heel

In adolescence and in adult life congenital flatfoot usually continues to show extreme ligamentous relaxation. Rarely is there spasticity in the peroneal muscles so commonly found in other types of flatfoot. The

severity of the deformity is usually greater also in congenital flatfoot, with excessive movement at the tarsometatarsal joint⁹. Congenital flatfoot responds very slowly to treatment. Arthritis and changes in the shape of the tarsal bones are often found in the second decade. The symptoms will depend on the severity of the strain. Lasting relief of symptoms is rarely observed in congenital flatfoot when treatment is not begun during the first decade of life. Adult patients can usually be made comfortable temporarily with apparatus, but occupations that require prolonged standing and walking cannot be followed¹⁰.

The pathogenesis and the background on which congenital flatfoot develops are not clearly understood. We have no acceptable explanation for the great differences in severity found in children. Heredity seems to play a part in its causation. In every instance in which a careful inquiry was made a history of a similar disability was found in the family of one or both ancestors. Sufficient data are not yet available, but what evidence there is suggests that it behaves like a recessive trait¹¹. It has been suggested that prenatal or early

Fig 3—Posterior view of the same feet as in figure 2. There is valgus of the os calcis.

rickets or some other nutritional disturbance might be the cause of the muscular and ligamentous relaxation,¹ but no evidence of such nutritional disturbances has yet been forthcoming. Bohm¹³ has postulated a failure of the foot to develop from the intrauterine position of valgus of the ankle joint and varus of the subastragalar joint. The position in utero with accompanying torsion of the tibias is no longer considered a valid explanation¹⁴.

Because the deformity of the foot is progressive without treatment, and because disability becomes severe in adult life, treatment should be started as soon as the condition is recognized. This treatment should be continued without interruption during early childhood until the foot is able to assume a normal position on weight bearing. Half hearted measures are entirely

ineffective. Not all patients will require treatment for the same length of time. The less severe disabilities will respond to treatment more readily and will require less elaborate apparatus in the after-care. Treatment must be both local (for the feet) and general (for the child as a whole). Adequate nutrition and sufficient rest and exercise are prerequisites to local treatment.

In infancy, when the foot shows extreme relaxation or a tendency to lie in calcaneovalgus, the most effective treatment is some form of support which holds the foot in inversion and plantar flexion at all times, except when the foot is bathed. Braces may be used but the simplest apparatus is a light plaster cast, which may be coated with a waterproofing compound (fig 6). This cast is cut into an upper and a lower half in order that it may be removed when necessary. The use of this cast leads to a gradual adaptive shortening of the relaxed muscles, especially those which pull the foot into inversion and plantar flexion. The time when the cast is to be discontinued is determined by the return of the normal limitation of motion in dorsiflexion and eversion and by the correction of the well defined

Fig 4—Congenital flatfoot of a child of 5 years. There is delayed osseous development. The osseous center for the scaphoid bone is just visible. There is no evidence of the third cuneiform.

ligamentous relaxation. Daily gentle manipulation of the feet by the nurse into inversion and plantar flexion is sometimes helpful.

When the child begins to stand, support which the child can use in walking should be provided. It is our aim to hold these congenital flat feet in an overcorrected position both when the child is in bed and when he is standing until he is able to stand with little displacement of the midtarsus and with little depression of the longitudinal arch. This overcorrected position is one of elevation of the longitudinal arch with the hind part of the foot, especially the os calcis,¹⁵ held in varus. A short caliper brace with attached foot plate is indicated in the severe ones. Usually, however, a felt or rubber pad under the entire longitudinal arch, high enough to correct any inward and downward displacement of the astragalus and scaphoid, is adequate if combined with a lift on the inner side of the heel to correct the valgus of the os calcis. This pad is most conveniently put into an innersole, so that it may be changed from one shoe to another. Foot plates are equally effective but are usually not as comfortable for small children (fig 7).

In addition to the pad in the shoe a slight raise on the inner side of the heel of the shoe is also given to tilt the os calcis into slight inversion. I have found it effective to raise the front inner corner of the heel and as far forward as the internal cuneiform (fig 3 B). The lift is usually $\frac{1}{8}$ to $\frac{1}{16}$ inch for children under

Fig 5—Anteroposterior and lateral views of congenital flatfoot of a child of 12 years. The scaphoid is depressed and the longitudinal arch of the foot is flattened. In the anteroposterior view there is medial and posterior projection of the astragalus.

4 years of age and $\frac{1}{4}$ to $\frac{1}{2}$ inch for children beyond this age. We do not raise the sole of the shoe under the ball of the foot. When the child first walks the plaster casts that hold the feet in inversion and plantar flexion are worn only at night. Sufficient shortening may have occurred in the relaxed supporting muscles and ligaments to permit the removal of the casts entirely by this time. But usually they are worn for at least two years. When the foot cannot be brought into more

Fig 6—Plaster casts used in the treatment of congenital flatfoot. These hold the feet in inversion and plantar flexion.

than 30 degrees of eversion or more than 40 degrees of dorsiflexion, the wearing of the plaster casts at night is no longer required.

When the child is able to carry out simple commands, active exercises for the feet are added to the treatment. These are given in order to secure a habitual

position of standing and walking in which the weight is carried on the outer side of the foot. Walking along a line with the foot in slight inversion and standing with the feet parallel with the knee cap rolled outward are probably the simplest of these exercises.¹⁶ An attempt should be made to correct the posture of the child at the same time, since weakness of the glutei usually associated with faulty posture adds to the disability of the feet and hinders proper use of the supporting musculature.¹⁷ The feet are an inseparable part of the body and the entire child must be considered in the alignment and weight carriage.

With the persistence in such treatment, correction of severe congenital flatfoot is possible in the first decade. Exercises and supports in the shoes are usually necessary, however, for the entire growing period. When the child can maintain the foot in a good weight bearing position with little downward displacement of the longitudinal arch and no eversion of the heel, support for the foot may be discontinued. By these measures at the present time we are able to correct about 50 per cent of congenitally flat feet. These corrected feet have no disability and show no deformity. It is our belief

Fig. 7—Diagram of insole. A lift of leather on the heel to tilt the os calcis into varus with a support under the longitudinal arch to prevent the depression of the longitudinal arch. These corrections are attached to an insole worn in the shoe.

that few congenitally flat feet would require any further treatment if these or similar measures were carried out for a prolonged period of time. Parents and physicians still take too complacent an attitude in regard to this serious disability.

No operative procedures for the feet should be undertaken, even when there is serious disability, before the age of 12 years. Most symptoms can be relieved, even in adults, with proper shoes and with supports under the longitudinal arch. But after 12, and preferably when full bony development has occurred, in the presence of serious disability, operative correction is indicated. There are a number of operative procedures available, depending on the severity of the condition. Tenodeses or transplantations of the tendons alone have not been effective in our experience.¹⁸ For the less extensive relaxations with little osseous deformity, arthrodesis of the astragaloscaphoid joint¹⁹ or scapho-

cuneiform joint may be sufficient. These procedures prevent displacement of the midtarsus downward and inward and disturb the flexibility of the foot very little. If a more extensive procedure is required, further arthrodeses may be performed, particularly along the medial side of the foot. Operations which secure correction and obtain stability and still do not sacrifice all movement in the posterior tarsal bones are preferable, such as those described by White²⁰ and Miller.²¹ If there is arthritis or much distortion of the subastragaloid joint, the joint should be fused, but usually it is better not to stiffen this joint. The operation should correct deformity completely and permit weight bearing without strain. After operation the foot is held in plaster and later by foot supports in slight inversion and with a little elevation of the longitudinal arch until the operation on the tarsus is solidly healed. During this time exercises are given to develop proper coordination in the supporting muscles of the foot.

CONCLUSIONS

1 Congenital flatfoot is a relatively common disability appearing in varying severity in about 0.5 per cent of all small children.

2 It is recognized in infancy by the extreme ligamentous relaxation about the foot and by the tendency of the foot to go into calcaneovalgus.

3 With growth, serious deformity and disability appear. Changes are found in the posterior tarsal bones, particularly the astragalus and scaphoid.

4 The cause is not clear but available data suggest that it is inherited, behaving like a recessive trait.

5 Treatment should be started in early childhood. The foot should be held while at rest and in weight bearing in inversion and with slight elevation of the longitudinal arch.

6 In cases of congenital flatfoot which are not corrected by this treatment, relief of symptoms can often be secured by proper shoes and by supports under the longitudinal arch and the inner side of the heel. For severe disability seen in adolescence or adult life, surgical procedures which will hold the foot in a good weight bearing position are usually required.

372 Marlborough Street

ABSTRACT OF DISCUSSION

DR W. LAPIDUS, New York. I agree with Dr. Kuhns when he looks on the idiopathic flat foot as a congenital hereditary malformation. It has been my increasing conviction that the flat foot must be considered as an arrest of ontogenetic development of the foot. This point of view is borne out by embryology, evolution and the comparative anatomy of the foot. Man is the only primate possessing a longitudinal arch. The foot of the early embryo is flat and does not begin to show any evidence of longitudinal arching before the end of the third month. From this time on the longitudinal arch gradually grows in its height, and its development continues long after birth and is not completed until adulthood. No plastic surgeon would attempt to reshape the nose of an 8 or 10 year old child, since at his age the facial features have not yet reached their permanent configuration. The same is true about the shape of the foot, and yet not infrequently reconstructive operations

for flat foot are performed in young children. The congenital flat foot should be looked on as a foot which became arrested in the earlier stages of ontogenetic development and failed to grow as old as the individual himself. The hypermobility of the flat foot in an adult due to ligamentous laxity corresponds to similar hypermobility of the foot in a young child and in an adult age. The generally accepted possibility of the development of an idiopathic flat foot from an originally normal one is doubtful. The development of a perfectly normal arch toward adulthood from a decidedly flat foot in childhood has been observed by me in several cases. Immobilization in plaster of paris and braces should be reserved for cases of extreme deformities, which fortunately are rare. The rigidity of the foot associated with peroneal spasm and osteoarthritic changes is a late secondary condition superimposed on the original deformity. Operative treatment of common flat foot, especially talonavicular fusion, should be discouraged. The results of twenty-seven operations with variable techniques performed on twenty-four idiopathic flat feet between 1930-1935 and reported by me before the New York Academy of Medicine about six years ago were rather disappointing. On the other hand, several children in the same series with pronounced deformity in whom no consent for operation was obtained developed toward adulthood practically normal looking and much more serviceable feet than did those in whom operations had been performed. The number of poor postoperative results increased with the number of years elapsing since operation was performed. Therefore for the past six years I have not operated in a single case of idiopathic flat foot.

DR. GUY A. CALDWELL, New Orleans. Dr. Kuhns has adequately described this group of cases. I have employed the plan of treatment practically as Dr. Kuhns has outlined it. Treatment of congenital flat foot during infancy is certainly beneficial in many cases and I have observed that in growing children conservative treatment is not always satisfactory. I have noted that with indifferent treatment some children have improved whereas others who followed most of the same measures prescribed by Dr. Kuhns failed to progress satisfactorily. I have been fatalistic about this condition, and I must confess that it has seemed to me that some literally outgrow it while others do not. Those who do not should be operated on, because their disability in later life is real. I believe that the age at which Dr. Kuhns has indicated operative treatment is correct. I have tried all the procedures described by Dr. Kuhns and I usually institute one of them. The Lowman operation for transplanting the anterior tibial tendon has given good results in a number of cases, and in a few the results have been poor. Operations which involve some change in the contour of the tarsal bones with fusion of the astragaloscaphoid and other joints, such as Miller and White have described, have been followed by good results in some cases and improvement in others, but results have not been uniformly ideal. I wonder if the indifferent results from these various procedures are caused by failure to correct the valgus position of the heel. No operation which consists of less than subastragalar arthrodesis will change the position of the heel materially. Unless this can be done the mechanical effects of the valgus heel cannot be entirely overcome. However, subastragalar arthrodesis certainly is not the ideal procedure for this condition, although when arthritic changes have set in it becomes the lesser of two evils.

DR. JOHN G. KUHNS, Boston. I agree with most of the things that have been said. My experience has not been quite as happy as that of Dr. Lapidus, but I have found that I have always been happier if I overtreated these feet than if I undertreated them. I have seen no spontaneous improvements. Probably we are speaking of a little different type of feet, because I consider the condition congenital flat foot only if there is extreme relaxation, particularly on the inner side of the foot. I agree with Dr. Caldwell that when we are faced with operative procedures we should do the least possible thing that will bring the foot and hold it in a good weight bearing position.

BISMARSEN (BISMUTH ARSPHENAMINE SULFONATE) FOR TREATMENT OF SYPHILIS

A REVIEW OF FOURTEEN YEARS' EXPERIENCE

HERMAN BEERMAN, MD

BERTRAM SHAFFER, MD

PHILADELPHIA

AND

CLARENCE S. LIVINGOOD, MD

INDIANTOWN GAP, PA

Bismarsen (bismuth arspenamine sulfonate), an arspenamine-bismuth compound synthesized by Dr. G. W. Raiziss¹ in 1924, has been subjected to clinical investigation in the department of dermatology and syphilology of the University of Pennsylvania School of Medicine since 1925. It was first used in the treatment of syphilis by Stokes and Chambers² who in 1927 reported on two years of observation of its effects. In 1931 Stokes, Miller and Beerman³ reported a summary of three more years' experience with the use of the drug in clinical practice, the results of a reexamination of 94 of the original 204 patients and a summary of the literature up to that date. This study revealed that bismarsen is a relatively nontoxic and easily administered drug for the treatment of patients with syphilis. The incidence of local reactions was low (2 per cent of injections), and systemic reactions occurred after only 0.5 per cent of the injections, or in 11 per cent of the patients. The systemic reactions included nitritoid crises, mild gastrointestinal reactions and cutaneous reactions. The first case of aleukemia hemorrhagica from this drug was noted (1 case for 11,000 injections). Three cases of jaundice were collected from the literature. There were no cerebral reactions. The drug was found to be a valuable substitute for other arspenamines in the treatment of many reactive patients. It was found to have an apparently good effect in early syphilis, in spite of slower healing and spirillicidal action, it had a good effect on reversal of the serologic reaction of the blood in early syphilis and apparently prevented abnormalities in the cerebrospinal fluid. For early syphilis the incidence of relapse of all forms was only 12 per cent. There was a suggestion that cardiovascular syphilis could progress under cover of treatment with bismarsen in early syphilis, as with other drugs and systems. Continuous treatment was found to be superior to intermittent treatment. The drug reduced about half of resistant positive serologic reactions of the blood to negative in various phases of the disease. Definite tonic effects were secured by treatment with it. In cardiovascular syphilis the drug yielded a good final result in 13 of 22 cases. Also when used alone it afforded patients with cardiovascular syphilis symptomatic relief equal to that secured when it was used in addition to iodide.

Dr. Beerman is Abbott Fellow in Chemotherapeutic Research. Contribution for the Abbott Fellowship in Chemotherapeutic Research. Read before the Section on Dermatology and Syphilology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

From the Department of Dermatology and Syphilology, University of Pennsylvania School of Medicine, and the Institute for the Control of Syphilis, John H. Stokes, M.D., director.

³ Stokes, J. H., Miller, T. H. and Beerman, Herman. An Appraisal of the Newest Arspenamine Synthetic Bismarsen in the Treatment of Syphilis, *Arch. Dermat. & Syph.* 23: 624 (April) 1931.

and mercury. In prenatal syphilis the action of the drug, while not fully appraised, seemed somewhat disappointing. Its slowness of action made it second choice for the treatment of acute interstitial keratitis. Its tonic effects were valuable. As a rule it had little good effect when used alone in the treatment of neurosyphilis, although certain types of neurosyphilis, particularly tabes dorsalis with lightning pains seemed to be greatly benefited. Since this study was made, numerous reports have appeared on the use of bismarsen in various phases of syphilis.⁴ In addition, recent studies emphasizing certain reaction tendencies⁵ and the use of this drug for conditions other than syphilis have been reported.⁶

We have undertaken the present study in order to reevaluate our experience with bismarsen as used over a period of fourteen years in the department of dermatology and syphilology of the Hospital of the University of Pennsylvania.

MATERIAL

In this study 823 patients received a total of 18,286 injections. They were fairly evenly divided among white and Negro and male and female patients (432 white, 391 Negro, 409 male and 414 female). Of them 299 had latent and Wassermann-fast syphilis, 151 had prenatal syphilis, 57 had late cutaneous and osseous syphilis, 117 had early syphilis, 101 had cardiovascular syphilis and 98 had syphilis of the central nervous system. Their ages ranged from 1 to 74 years. The range of ages on admission was that usually found for patients with the various phases of syphilis studied. Bismarsen was administered whenever possible twice a week and in uninterrupted courses of 60 injections or more, with the treatment tapered off with injections of a bismuth preparation. Many of the patients were not treated exclusively with bismarsen. This is especially true of the patients to whom bismarsen was given because of some reaction to another arsenical. Furthermore many of the patients with newly acquired early syphilis have been subjected to other forms of treatment under investigation since 1932. As many patients as possible were subjected to complete reexamination with special reference to the cardiovascular and the central nervous system, serologic tests of the blood for syphilis and examination of the cerebrospinal fluid. In addition, special consultation was had with the cardiologist, the neurologist and the ophthalmologist whenever possible, and special laboratory studies and roentgenologic studies were made when indicated.

LOCAL AND GENERAL REACTIONS TO BISMARSEN

Whereas the 1931 study³ showed that 2 per cent of the injections had produced local reactions sufficient to be notable (percentage of patients affected, 35.5), in this evaluation, 0.85 per cent of the injections yielded local reactions (percentage of patients affected, 18.8). As was previously noted, local reactions were considerably fewer in the patients with prenatal syphilis, since only 8 per cent of these patients had such reactions. This experience differs from that of Yampolsky,⁸ who stated the belief that bismarsen causes considerable pain in children. General reactions were for the most part mild, 135 such reactions occurred among the 823 patients. They consisted of gastrointestinal reactions, 58 cases, chills and fever, 28 cases, nitritoid crises, 19 cases, pruritus with or without dermatitis, 11 cases, arspenamine dermatitis, 5 cases, hemorrhagic purpura, 5 cases, blue line of the gums, 2 cases, urticaria, 2 cases, nondescript eruption, 2 cases, headache, 1 case, in eruption like pityriasis rosea, 1 case, and abdominal cramps, 1 case. While this incidence of general reactions is higher than was previously reported by this group (16.2 per cent as compared with 11 per cent of patients), emphasis must be placed on the fact that in recent years the tendency has been to use bismarsen more and more in the treatment of patients who have had reactions to various other arsenicals, of which special mention will be made hereafter. Our figure (0.75 per cent) compares favorably with that of Thurman and Tolman,⁹ who in the department of dermatology and syphilology of the Boston Dispensary, found 1.6 per cent of injections producing reactions in patients who for the most part were being treated with bismarsen because they were unable to tolerate other arsenicals injected intravenously.

Recent interest, as expressed by a number of reports on hemorrhagic reactions to bismarsen, deserves special consideration. Stokes, Miller and Beerman reported the first case of hemorrhagic purpura. Niles¹⁰ (1934) reported this reaction in a man who, although treated with bismarsen, had had a great deal of previous anti-syphilitic therapy, to all of which he reacted in some degree and who twenty-two months previously had had the same type of reaction after the use of sulfarsphenamine. Grund's¹¹ patient too had previously had purpura from neoarsphenamine. Wyatt¹² reported in 1939 a case of peripheral neuritis from neoarsphenamine in which hemorrhagic purpura subsequently developed from bismarsen. Falconer and Epstein,¹³ who reported 5 cases of thrombopenia and purpura, in 2 of which the reaction followed intravenous injections of neoarsphenamine and in 3 of which it occurred after intramuscular injections of bismarsen, concluded from their observations and studies made after test doses of the arsenamines to which these patients were sensitive that

varying degrees of shock occurred, suggesting that the reaction was an allergic phenomenon rather than due to the toxic effects of oxidation or to a changed chemical form.

of the drug injected. The prompt loss of circulatory tone accompanying the reaction appears to be a vasomotor effect, with loss of capillary tonus, dilatation of the capillary bed and a rapid loss of platelets from the general circulation. It is difficult to believe that such enormous numbers of platelets could be destroyed within fifteen minutes after the drug is injected. The fact that a great number of platelets can be returned promptly into the general circulation by injection of 1 cc of epinephrine hydrochloride (1:1,000 solution) and the rapid rise of the platelet count within twenty-four to forty-eight hours after the reaction, are evidence against the assumption of widespread destruction of the platelets.

The blood cells other than the platelets showed little if any change during these experiments. There appeared to be a tendency to an increase of the polymorphonuclear cells following a reaction, particularly a severe reaction. This may well be a phenomenon similar to the leukocytosis associated with protein shock.

We have observed no deaths due to bismarsen, although Swartz, Tolman and Levine¹⁴ in 1936 reported a fatal case of fat embolism following the use of this preparation. They attributed the reaction to the arsphenamine radical common to bismarsen and the other arsenical compounds.

Stokes, Miller and Beerman found bismarsen a useful substitute in the treatment of reacting patients. Further experience has confirmed this earlier view, but we are not in favor of extensive use of another arsenical in place of one which has produced a serious arsphenamine reaction. In the case of mild reactions, our more extended experience has indicated that in about two thirds of cases of gastrointestinal reactions to arsphenamine, neoarsphenamine and trisodium arsphenamine sulfonate, bismarsen may be used without fear of recurrence of the reaction. As to patients with nitritoid reactions and chills and fever from the various arsenicals, about half may receive bismarsen therapy with no recurrence of the reaction. Bismarsen may be tried cautiously in the treatment of patients who have recovered from jaundice induced by other arsenicals. Although we found 6 cases of pruritus and 1 in which the patient had recovered from arsphenamine dermatitis due to other arsenicals but tolerated bismarsen well, we do not feel that except under expert guidance further arsenical therapy should be tried in such cases.

BISMARSEN IN PRIMARY AND SECONDARY SYPHILIS

In the earlier reports, as well as in more recent reports, it has been indicated that bismarsen is an effective drug in the management of early syphilis. It has the drawback, however, of being somewhat slower in the healing effect and spirillicidal action which are demanded of a drug for present day public health qualifications. This apparent defect is overcome by a consideration of the end results of bismarsen therapy. Our present results in regard to healing effect, spirillicidal effect and symptomatic response are essentially the same as those reported by Stokes, Miller and Beerman because most of the patients with newly acquired early syphilis recently treated in our clinic have been given other drugs which were under investigation, and patients who had reacted to other drugs were then given bismarsen.

Healing Effect and Spirillicidal Action—The healing of primary lesions took place between the fifth and the thirteenth injection, and secondary lesions healed after an average of about 4 injections, or in seventeen

days. The spirillicidal action occurred within an average of seventy-four and one-half hours.

Herxheimer Reaction—Four patients were observed with the Herxheimer reaction.

Effect on the Serologic Reactions of the Blood and on the Cerebrospinal Fluid—No significant new data were obtained with regard to reversal of the serologic reaction of the blood in early syphilis. In the few additional fresh cases of early syphilis in which the patient was given bismarsen and treated with it exclusively, this reversal occurred after an average of 146 injections in ninety-eight and seven-tenths days. Serologic reversals in early syphilis were usually permanent. Of 71 patients with early syphilis observed for periods ranging from six months to fourteen years, serologic relapse occurred alone in 4 patients and in conjunction with an infectious mucocutaneous relapse in 4 additional patients (11.3 per cent, as compared with 14 per cent of 258 patients with serologic relapse under treatment for more than six months in the Cooperative Clinical Group study).¹⁵

In 48 patients one or more examinations of the cerebrospinal fluid were made. In 6 the fluid was found to be abnormal. Of these 6, 2 had previously been reported on by Stokes, Miller and Beerman. One of these was reexamined in 1939. The serologic reaction of the blood was negative, but no repeat examination of the cerebrospinal fluid could be made. The other patient could not be found for reexamination. Of the 4 new patients with abnormal spinal fluid the abnormality in 1 can hardly be attributed to bismarsen therapy. He is one of the two brothers involved in a case of transfusion syphilis reported by Livingood and Beerman.¹⁶ A boy of 10, treated adequately with bismarsen, whose first cerebrospinal fluid test after treatment, gave negative results, had a positive reaction to a cerebrospinal fluid test when reexamined several years later. His brother's syphilis, treated with neoarsphenamine and bismuth, had a similar outcome. The patient and his brother were considered to have either a constitutional factor or a neurotropic strain of *Spirochaeta pallida* to account for this unusual course. Another of the 4 patients with positive results of cerebrospinal fluid examinations was a man who was treated first with trisodium arsphenamine sulfonate but because of reactions to this drug was then given bismarsen somewhat irregularly. His cerebrospinal fluid was type 2, but after 41 additional injections of bismarsen one and one-half years later, reexamination of the cerebrospinal fluid gave negative results. The third patient had received only 15 injections of bismarsen after 17 injections of neoarsphenamine and 12 of bismuth compounds. When his cerebrospinal fluid was reexamined three years later (after a total of 15 injections of bismarsen, 17 of neoarsphenamine, 11 of tri-arsenamide and 64 of a bismuth compound) its reaction was completely negative. The fourth patient had type 3 cerebrospinal fluid after 41 injections of bismarsen, but no recent study of the fluid has been made.

In the follow-up study of all the patients with early syphilis, 48 patients had one or more examinations of the cerebrospinal fluid during the total period of their observation, and only the 6 mentioned showed any degree of abnormality. This experience suggests that

and mercury. In prenatal syphilis the action of the drug, while not fully appraised, seemed somewhat disappointing. Its slowness of action made it second choice for the treatment of acute interstitial keratitis. Its tonic effects were valuable. As a rule it had little good effect when used alone in the treatment of neurosyphilis, although certain types of neurosyphilis, particularly tabes dorsalis with lightning pains seemed to be greatly benefited. Since this study was made, numerous reports have appeared on the use of bismarsen in various phases of syphilis.⁴ In addition, recent studies emphasizing certain reaction tendencies⁵ and the use of this drug for conditions other than syphilis have been reported.⁶

We have undertaken the present study in order to reevaluate our experience with bismarsen as used over a period of fourteen years in the department of dermatology and syphilology of the Hospital of the University of Pennsylvania.

MATERIAL

In this study 823 patients received a total of 18,286 injections. They were fairly evenly divided among white and Negro and male and female patients (432 white, 391 Negro, 409 male and 414 female). Of them 299 had latent and Wassermann-fast syphilis, 151 had prenatal syphilis, 57 had late cutaneous and osseous syphilis, 117 had early syphilis, 101 had cardiovascular syphilis and 98 had syphilis of the central nervous system. Their ages ranged from 1 to 74 years. The range of ages on admission was that usually found for patients with the various phases of syphilis studied. Bismarsen was administered whenever possible twice a week and in uninterrupted courses of 60 injections or more, with the treatment tapered off with injections of a bismuth preparation. Many of the patients were not treated exclusively with bismarsen. This is especially true of the patients to whom bismarsen was given because of some reaction to another arsenical. Furthermore, many of the patients with newly acquired early syphilis have been subjected to other forms of treatment under investigation since 1932. As many patients as possible were subjected to complete examination with special reference to the cardiovascular and the central nervous system, serologic tests of the blood for syphilis and examination of the cerebrospinal fluid. In addition, special consultation was had with the cardiologist, the neurologist and the ophthalmologist whenever possible, and special laboratory studies and roentgenologic studies were made when indicated.⁷

of the drug injected. The prompt loss of circulatory tone accompanying the reaction appears to be a vasomotor effect, with loss of capillary tonus, dilatation of the capillary bed and a rapid loss of platelets from the general circulation. It is difficult to believe that such enormous numbers of platelets could be destroyed within fifteen minutes after the drug is injected. The fact that a great number of platelets can be returned promptly into the general circulation by injection of 1 cc of epinephrine hydrochloride (1:1,000 solution), and the rapid rise of the platelet count within twenty-four to forty-eight hours after the reaction, are evidence against the assumption of widespread destruction of the platelets.

The blood cells other than the platelets showed little if any change during these experiments. There appeared to be a tendency to an increase of the polymorphonuclear cells following a reaction, particularly a severe reaction. This may well be a phenomenon similar to the leukocytosis associated with protein shock.

We have observed no deaths due to bismarsen, although Swartz, Tolman and Levine¹⁴ in 1936 reported a fatal case of fat embolism following the use of this preparation. They attributed the reaction to the arsenphenamine radical common to bismarsen and the other arsenical compounds.

Stokes, Miller and Beerman found bismarsen a useful substitute in the treatment of reacting patients. Further experience has confirmed this earlier view, but we are not in favor of extensive use of another arsenical in place of one which has produced a serious arsenphenamine reaction. In the case of mild reactions, our more extended experience has indicated that in about two thirds of cases of gastrointestinal reactions to arsenphenamine, neoarsphenamine and trisodium arsenphenamine sulfonate, bismarsen may be used without fear of recurrence of the reaction. As to patients with nitritoid reactions and chills and fever from the various arsenicals, about half may receive bismarsen therapy with no recurrence of the reaction. Bismarsen may be tried cautiously in the treatment of patients who have recovered from jaundice induced by other arsenicals. Although we found 6 cases of pruritus and 1 in which the patient had recovered from arsenphenamine dermatitis due to other arsenicals but tolerated bismarsen well, we do not feel that except under expert guidance further arsenical therapy should be tried in such cases.

BISMARSEN IN PRIMARY AND SECONDARY SYPHILIS

In the earlier reports, as well as in more recent reports, it has been indicated that bismarsen is an effective drug in the management of early syphilis. It has the drawback, however, of being somewhat slower in the healing effect and spirillicidal action which are demanded of a drug for present day public health qualifications. This apparent defect is overcome by a consideration of the end results of bismarsen therapy. Our present results in regard to healing effect, spirillicidal effect and symptomatic response are essentially the same as those reported by Stokes, Miller and Beerman because most of the patients with newly acquired early syphilis recently treated in our clinic have been given other drugs which were under investigation, and patients who had reacted to other drugs were then given bismarsen.

Healing Effect and Spirillicidal Action—The healing of primary lesions took place between the fifth and the thirteenth injection, and secondary lesions healed after an average of about 4 injections, or in seventeen

days. The spirillicidal action occurred within an average of seventy-four and one-half hours.

Heilheimer Reaction—Four patients were observed with the Heilheimer reaction.

Effect on the Serologic Reactions of the Blood and on the Cerebrospinal Fluid—No significant new data were obtained with regard to reversal of the serologic reaction of the blood in early syphilis. In the few additional fresh cases of early syphilis in which the patient was given bismarsen and treated with it exclusively, this reversal occurred after an average of 14.6 injections in ninety-eight and seven-tenths days. Serologic reversals in early syphilis were usually permanent. Of 71 patients with early syphilis observed for periods ranging from six months to fourteen years, serologic relapse occurred alone in 4 patients and in conjunction with an infectious mucocutaneous relapse in 4 additional patients (11.3 per cent, as compared with 14 per cent of 258 patients with serologic relapse under treatment for more than six months in the Cooperative Clinical Group study).¹⁵

In 48 patients one or more examinations of the cerebrospinal fluid were made. In 6 the fluid was found to be abnormal. Of these 6, 2 had previously been reported on by Stokes, Miller and Beerman. One of these was reexamined in 1939. The serologic reaction of the blood was negative, but no repeat examination of the cerebrospinal fluid could be made. The other patient could not be found for reexamination. Of the 4 new patients with abnormal spinal fluid the abnormality in 1 can hardly be attributed to bismarsen therapy. He is one of the two brothers involved in a case of transfusion syphilis reported by Livingood and Beerman.¹⁶ A boy of 10, treated adequately with bismarsen, whose first cerebrospinal fluid test after treatment, gave negative results, had a positive reaction to a cerebrospinal fluid test when reexamined several years later. His brother's syphilis, treated with neoarsphenamine and bismuth, had a similar outcome. The patient and his brother were considered to have either a constitutional factor or a neurotropic strain of *Spirochaeta pallida* to account for this unusual course. Another of the 4 patients with positive results of cerebrospinal fluid examinations was a man who was treated first with trisodium arsenphenamine sulfonate but because of reactions to this drug was then given bismarsen somewhat irregularly. His cerebrospinal fluid was type 2, but after 41 additional injections of bismarsen one and one-half years later, reexamination of the cerebrospinal fluid gave negative results. The third patient had received only 15 injections of bismarsen after 17 injections of neoarsphenamine and 12 of bismuth compounds. When his cerebrospinal fluid was reexamined three years later (after a total of 15 injections of bismarsen, 17 of neoarsphenamine, 11 of trypanarsamide and 64 of a bismuth compound) its reaction was completely negative. The fourth patient had type 3 cerebrospinal fluid after 41 injections of bismarsen, but no recent study of the fluid has been made.

In the follow-up study of all the patients with early syphilis, 48 patients had one or more examinations of the cerebrospinal fluid during the total period of their observation, and only the 6 mentioned showed any degree of abnormality. This experience suggests that

bismarsen has a good sustained record of preventing neurosyphilis in patients with early syphilis if treatment is adequate

Relapse—Eleven patients with early syphilis showed one or more forms of relapse. 5 had clinical relapse, 8 had serologic relapse (4 of these also had clinical relapse) and 2 had neurorecurrence (1 of these also had serologic relapse). The percentage of all forms of relapse in patients with early syphilis after treatment exclusively or preponderantly with bismarsen and after observation for six months or more is 13.4 (82 cases). This figure compares favorably with the 12 per cent found in the Stokes, Miller and Beerman study of 1931. If only clinical relapse of all types irrespective of the duration of observation is considered, the figure is 11.3 per cent. The Cooperative Clinical Group¹ found the total incidence of relapse in their patients to be 10.1 per cent. If only the patients treated for six months or longer were considered, the figure was 19.7 per cent.

Reexamination—Of all patients with early syphilis treated with bismarsen, 39 were reexamined one or more times. Twelve were observed for one to five years, 19 from five to ten years and 18 from ten to fourteen or more years after infection was detected. Of these 40, only 3 showed any type of progression. In 2 cardiovascular syphilis developed, in 1 after 40 and in the other after 10 injections of bismarsen, and 1 had neurorecurrence. Two patients were dead, one had committed suicide and the cause of death of the other was unknown. This relatively low incidence of progression speaks favorably for bismarsen.

BISMARSEN IN LATENT AND WASSERMANN-FAST SYPHILIS

As noted previously by Stokes, Miller and Beerman changes in the serologic status of the blood, clinical progression of the disease and tonic effects are the only criteria of the beneficial results of therapy in latent syphilis. The patients in this study with latent syphilis who were not included in the Stokes, Miller and Beerman review were given bismarsen largely because of reactivity to other arsenicals and often after previous treatment had been contraindicated for other reasons. In addition, there were 40 patients whose data were not suitable for analysis because they were seronegative before treatment was started. Therefore, of the 299 patients with latent syphilis, only 92 had data eligible for full analysis. Fifteen of these had fixed positive serologic reactions of the blood, 41.3 per cent of this total group (38 patients) underwent a reversal to negative, and about half of the patients with fixed positive reactions had a reversal to negative. In confirmation of our previous impression, our data suggest that if serologic reversal takes place at all it occurs relatively early after bismarsen therapy is begun rather than after a long series of injections.

Patients with latent syphilis whose treatment was begun after the Stokes, Miller and Beerman report of 1931 were found to sustain weight gains and other tonic effects, as previously noted.

Of the 299 patients with latent syphilis, 121 had had one or more reexaminations since 1931. Of the group reported on in 1931, 16 had examinations prior to 1931 and during the interim. Twenty-eight of these patients were observed from one to five years, 65 from five to ten years and 28 from ten to fourteen years. Of these 121 patients, there were only 4 in whom any signs of pro-

gression could be detected. One had questionable syphilis of the central nervous system, 1 had progression of syphilis of the central nervous system with a positive reaction of the spinal fluid, 1, who had received only 8 injections of bismarsen, had neurorelapse. He was normal in 1932 and had neurosyphilis in 1939. In 1 patient a murmur developed after 36 injections of bismarsen. Eight patients had died. The cause of the death of 7 was determined and none died of syphilis. The cause of death of the eighth patient was not determined. Of the 299 patients with latent syphilis, 143 had one or more cerebrospinal fluid examinations before during or after bismarsen therapy. Of these, 9 at some time or other had some abnormality. Three who had cerebrospinal fluid formulas of grades 1, 2 and 3, respectively, all had negative reports after further bismarsen therapy and observation. One patient who had a cerebrospinal fluid relapse progressed to clinical neurosyphilis. One whose spinal fluid examination gave positive results had received only 8 bismarsen injections, 4 whose cerebrospinal fluid examination gave negative results on admission were later found to have positive reactions. The fluid of 1 of these, however, had a formula of grade 3.

BISMARSEN IN CARDIOVASCULAR SYPHILIS

Because bismarsen was rated by Stokes, Miller and Beerman as both a safe and an effective drug in the treatment of aortic types of vascular syphilis, an opinion concurred in by Moore and his associates,¹⁷ we treated 70 patients with cardiovascular syphilis in addition to the 40 reported on by Stokes, Miller and Beerman. The patients we treated were usually elderly white persons or somewhat younger Negroes. In the new group there were 37 patients with aortitis, 2 with aortitis and beginning aneurysm, 7 with aortic aneurysm, 1 with carotid aneurysm, 10 with aortic regurgitation, 2 with aortic regurgitation and aneurysm, 2 with mitral stenosis which the cardiologists said was syphilitic, 1 with coronary occlusion, 7 with advanced cardiovascular disease and 1 with hypertension. (Three of the patients with cardiovascular disease had neurosyphilis.) Among the 40 patients previously studied, 20 had early aortitis, 9 had aortic regurgitation, 7 had aneurysm, 5 had mitral carditis and 6 had miscellaneous conditions.

No new serologic data could be obtained from study of our patients because most of them had previously received other therapy, with reversal of the serologic tests of the blood to negative. However, in 22 patients from 6 to 60 injections of bismarsen produced little effect on the serologic reactions of the blood (Kolmer, Kahn and Kline tests).

Twenty of the patients with cardiovascular syphilis had cerebrospinal fluid examinations after institution of bismarsen therapy. One patient whose spinal fluid had previously given a positive reaction (type 3) had a negative reaction and another whose fluid had previously given a positive reaction was not reexamined after institution of treatment.

Careful reexaminations, usually confirmed by the cardiologist with the aid of roentgenologic, electrocardiographic and other special studies, were made of 52 patients, and follow-up reports were obtained from official sources whenever possible on 33 patients who had died. The patients who had one or more reexami-

17 Moore, J. E., Danglade, J. H. and Reisinger, J. C. Treatment of Cardiovascular Syphilis. Results Obtained in Fifty Three Patients with Aortic Aneurysm and in One Hundred and Twelve with Aortic Regurgitation. Arch. Int. Med. 49: 879 (June) 1932.

nations had been observed up to fourteen years or more (one to five years, 30 patients, five to ten years, 17 patients, ten to fourteen or more years, 5 patients)

Of the patients with aortitis, 10 had improved, 14 showed no change, 3 were worse and there were no data on 25. Of those who died with aortitis, there were none whose death could be directly attributed to the syphilitic cardiac lesion. Of the patients with aortitis and beginning aneurysm, 1 was improved, the condition of 6 was the same, 3 had progressed unfavorably and 1 had died (cause of death undetermined). Of the patients with aneurysm, 1 had improved, the condition had remained stationary in 1 and 7 had died. Of the patients with aneurysm who had died, 1 received only 2, 1 only 4 and 1 only 5 injections of bismarsen, 1 died of pneumonia, 1 of tuberculosis with pulmonary hemorrhage and 2 of aneurysm. Of the patients with aortic regurgitation, 2 had improved, the status of 1 had not changed and 8 had died. Of the deaths, 3 could be attributed to progression of the syphilis. In 1 of the patients the cardiac lesion was advanced before bismarsen therapy was begun. Of the patients with miscellaneous types of syphilitic cardiac lesions, none were improved, 3 showed no change (1 of these subsequently died of coronary occlusion), 8 were worse and 10 had died. Of the 10 who died, the cause was not determined in 4 and in only 2 of the remaining 6 could blame be thrown on the advancing syphilitic heart disease.

From these data, considering the fact that our patients were largely poor risks to begin with, we feel that bismarsen is a safe and effective drug for patients with cardiovascular syphilis.

BISMARSEN IN PRENATAL SYPHILIS

Recent interest in the use of bismarsen in the treatment of prenatal syphilis is evidenced by the publications of Chambers and Koetter,¹⁸ Marks¹⁹ and Reilly.²⁰ All three studies indicate that bismarsen is an effective antisyphilitic agent which has added features of simplicity of administration and low toxicity.

Our clinical material comprises the 40 cases studied by Stokes, Miller and Beerman and 107 others. Our total group has the shortcomings stated by Stokes, Miller and Beerman in that the cases have little value for study of the acute effects of bismarsen, since they are largely instances of the equivalent of late latent acquired syphilis. They do have much value, however, from the standpoint of the ultimate effects of bismarsen treatment in the prevention of late manifestations of this phase of syphilis. We still feel that the slowness of action of bismarsen precludes its use in the treatment of acute interstitial keratitis.

No significant differences have been noted in the effect of bismarsen on the serologic reaction of the blood in prenatal syphilis from those expressed by Stokes, Miller and Beerman.

Cerebrospinal fluid examinations were made one or more times on 52 patients with congenital syphilis. Of these, 4 had positive reactions, 1 had a positive reaction of type 3 after 20 injections of bismarsen, which became a type 2 reaction after 41 injections and later a type 1 reaction. The use of other therapy was contra-

indicated. Another patient had a type 3 cerebrospinal fluid formula after treatment with bismarsen but had had no cerebrospinal fluid examination before bismarsen therapy (type 2). The reaction of the fluid became negative during treatment. The fourth patient with late prenatal syphilis, after 24 injections of bismuth salts and 34 of bismarsen, had a type 3 cerebrospinal fluid formula. This formula was maintained in spite of tryparsanamide therapy.

Aside from its specific effects in syphilis, bismarsen was found to produce weight gain and other tonic effects in patients with congenital syphilis.

Eighty-nine patients with congenital syphilis were reexamined in the course of the present study. These patients were observed from one to fourteen years (30 from one to five years, 40 from five to ten years and 19 from ten to fourteen years). Of these, 1 showed a relapse of interstitial keratitis after treatment was stopped, 1 with prenatal neurosyphilis had progression, while 1 with this type of neurosyphilis improved. No evidence of progression was noted in the remaining patients. Three of the patients had died. None of the deaths was due to syphilis.

Special mention must be made of our experience with interstitial keratitis. In 1 patient the interstitial keratitis disappeared after 9 injections of bismarsen, returned after 22, cleared quickly but relapsed after 30 injections of bismarsen and an eight month lapse of treatment. In another patient, previously well, interstitial keratitis developed during bismarsen therapy, an occasional occurrence under any form of treatment. A third patient, with Clutton's joints, responded well but interstitial keratitis developed in spite of bismarsen therapy. In a fourth patient interstitial keratitis relapsed. This patient had received 95 injections of bismarsen to 1933. In 1935 the serologic reactions of the blood and the reactions of the cerebrospinal fluid were negative. In 1938 the patient had interstitial keratitis in the left eye. This rather unpredictable experience with this ocular manifestation of prenatal syphilis is in keeping with our experience with other antisyphilitic drugs used for its treatment. The experience does not condemn any of the drugs but merely reemphasizes the need of an ideal treatment for this ocular condition (cf Givan and Villa²¹ and Klauder and Vandoren²²).

On the whole, as far as any therapy for prenatal syphilis can be estimated, bismarsen seems of value for the average patient. For patients with interstitial keratitis, other types of therapy (fever) combined with use of the arsenical are indicated.

BISMARSEN IN CUTANEOUS AND OSSEOUS GUMMA

In addition to the 35 patients reported on by Stokes, Miller and Beerman, we had 22 patients with osseous and cutaneous gumma. Most of these patients had received other therapy, but in 6 healing took place at a moderate rate while in 1 it took place with remarkable speed. On the whole, however, healing takes place more slowly with bismarsen than with the other arsenicals, bismarsen, however, may be used advantageously in the treatment of patients who, because of their poor physical status, may not tolerate other arsenicals. Of 23 patients reexamined, there were no signs of active syphilis in 22. Of the 23, 7 were observed up to five years, 6 from five to ten years and 6 from ten to four-

teen years. In 1 there was questionable neurosyphilis. Seven of the patients had died. Four of the deaths were not related to treatment, and the cause of 1 was unknown.

BISMARSEN IN NEUROSYPHILIS

Our interest in the use of bismarsen in the treatment of neurosyphilis has in the past centered chiefly on the symptomatic improvement of specific complaints and on serologic results. In our present data, based on a total of 98 patients with various types of neurosyphilis, including 17 with asymptomatic neurosyphilis, 49 with *tabes dorsalis*, 5 with the *tabetic* form of *dementia paralytica*, 10 with *dementia paralytica*, 12 with "central nervous system syphilis," 2 with vascular syphilis and 3 with miscellaneous types, our chief attention has been focused on ultimate results based on reexaminations of patients treated wholly or in part with bismarsen. It is necessary again to point out that many of our patients were not ideal risks before treatment was instituted. Seventy-five were 30 years of age or more and 56 were 40 or more on admission.

Treatment with as many as 60 injections of bismarsen had no effect on the cerebrospinal fluid formula of 11 patients with various types of neurosyphilis (formula types 2, 5 patients, 3, 6 patients). The cerebrospinal fluid formulas of 16 patients had improved and those of 5 patients were worse after treatment with bismarsen (type 2, 4; type 3, 1).

Fifteen patients with neurosyphilis died during the course of our observation. These patients had been observed for from one to thirteen years. Nine of this group (we had data on 10) died as a result of progression of the neurosyphilis.

Forty-five patients who were reexamined one or more times in the course of the present study had no evidence of progression of their neurosyphilis. Only one additional patient was better, and 4 were worse.

Aside from the previously reported subjective improvement in patients with neurosyphilis treated with bismarsen, we believe that for the treatment of such patients who are intolerant of fever or of other chemotherapy bismarsen is a useful substitute.

SUMMARY AND CONCLUSIONS

1 Bismarsen is a relatively nontoxic and easily administered drug for the treatment of syphilis. Although it was frequently used in treating patients who had shown unfavorable reactions to other arsenicals, its incidence of local and systemic reactions was relatively low, only 5 cases of *arsphenamine* dermatitis and 5 cases of hemorrhagic purpura among a total of 823 patients being observed. There were no fatalities.

2 Bismarsen has a good effect in early syphilis, but it results in slower healing and has a slower spirillicidal action than do other arsenicals. Its action in preventing progression, neurosyphilis and relapses of all types is excellent.

3 In latent syphilis the reversal of the fixed positive serologic reaction and the prevention of neurosyphilis and other forms of clinical syphilis are effectively accomplished by bismarsen.

4 Bismarsen is a safe and effective drug for the treatment of cardiovascular syphilis.

5 The late complications of congenital syphilis are controlled through the use of bismarsen. Its action is too slow, however, for the treatment of active interstitial keratitis, and, as with all antisiphilitic drugs, erratic flares and relapses may occur.

6 The treatment of cutaneous and osseous gummatous syphilis with bismarsen produces a uniformly favorable response, but the healing effect is slower than that of other arsenicals.

7 Use of bismarsen is not the treatment of choice for neurosyphilis, but for persons for whom fever therapy and other forms of chemotherapy are contraindicated it is a useful substitute.

THE USE OF BISMUTH COMPOUNDS IN SYPHILOTHERAPY

II. RESULTS OF TREATMENT OF LATENT SYPHILIS BY BISMUTH COMPOUNDS COMBINED IN PART WITH ARSENICALS

DAVID KAHN, M.D.

AND

S. WILLIAM BECKER, M.D.

CHICAGO

The use of bismuth compounds in the therapy of syphilis was discussed by Walsh and Becker in 1940.¹ From a review of the literature they concluded that although in some instances it will cure syphilis, it cannot be relied on as the sole antisiphilitic drug to the exclusion of the *arsphenamines*.² They reported excellent results from the treatment of early syphilis by means of bismuth given in about twice the usual amount and combined in part with an arsenical preparation. They also obtained good results in asymptomatic neurosyphilis and *tabes dorsalis* by a method which used prolonged bismuth therapy in place of the intensive measures such as fever, intraspinal and trypanamide therapy. Since this publication very few reports relative to treatment of syphilis by bismuth have appeared in the available literature. Carrera³ reported a small series of patients with early syphilis treated by means of liposoluble bismuth only. There were 7 with seronegative primary syphilis, 12 with seropositive primary syphilis and an unstated number with secondary syphilis. The serologic reactions had become negative in all instances and had remained so from one to two years. The cerebrospinal fluid of 10 patients was examined and was negative in all instances. Carrera stated that the results were as good as those obtained from combined arsenical-bismuth treatment. The other publications deal with complications from treatment and will be discussed later.

Our purpose in this report is to present the results in late latent syphilis obtained at the University of Chicago Clinics by the use of large amounts of bismuth combined with a moderate amount of an arsenical and compare them with the results reported by the Cooperative Clinical Group.⁴ Patients included in our group of late latent syphilis include those with asymptomatic syphilis who have had the disease for three or more years. The Cooperative Clinical Group places the dividing line between early and late latency at four

years. Nearly all our patients had been infected for four years or more, hence for practical purposes our material is comparable with the late latent cases in the Cooperative Clinical Group study. Approximately 30 per cent of their cases were of early latent syphilis, which tends to influence favorably the total results, since the outcome in early latency is better than in late latency. Our results in treating early latent syphilis have been reported previously in connection with the treatment of early syphilis.¹

The importance of treating latent syphilis is well stated by Moore, who points out that "nearly every patient with a late lesion of syphilis has passed through the stage of latency." Potential infectiousness for others, although slight in latent syphilis, is still a real enough hazard to indicate treatment. Other indications are the prevention of clinical progression or relapse and the prevention of the birth of syphilitic children.

Seventy-six white men and 124 white women ranging in age from 20 to 60 years were treated according to the system of therapy shown in table 1. Treatment consisted of a minimum of six courses of bismuth subsalicylate in oil (eight to ten weekly intragluteal injections), with rest periods of one month. A course of an arsenical (six to eight intravenous injections at weekly intervals) is given simultaneously with the second, fourth and sixth bismuth courses. Treatment is then continued with courses of bismuth at progressively longer intervals, namely three months, six months, and one year. A yearly course of bismuth is then given as long as the serologic test shows any degree of positivity. One cc of the bismuth subsalicylate in oil contained 0.057 to 0.060 Gm of metallic bismuth. The bismuth subsalicylate supplied by some manufacturers contains 0.075 or even 0.1 Gm of metallic bismuth per cubic centimeter, so that the amount given per treatment must be decreased slightly to compensate for the greater concentration. When treated for the full course outlined in table 1, each patient received a minimum of 6.5 to 7 Gm of metallic bismuth, those with persistently positive blood reactions received more.

Various arsenicals have been used in combination with bismuth subsalicylate. Formerly, arsphenamine or neoarsphenamine was given in courses of six weekly intravenous injections. An experimental arsenical thioarsene, was employed, entirely or in part, in 65 per cent of cases. This drug was shown to be an unsatisfactory preparation as compared with arsphenamine, when used alone or in alternation with bismuth. In recent years mapharsen has been the usual arsenical employed, a course consisting of eight weekly injections.

Our plan of therapy differs in several respects from the methods used by the five clinics in the Cooperative Clinical Group study. The cooperating clinics usually employed alternating courses of arsenical and heavy metal (bismuth or mercury) either continuously or intermittently. In our system of therapy treatment is always instituted with a course of bismuth, and subsequently the arsenical is given simultaneously with bismuth. Treatment was originally given twice a week, the arsenical and one half of the bismuth dose on one visit and the other half of the bismuth dose on the second visit. In recent years, for the convenience of the patients, who travel an average round trip distance of 13 miles, administration of the arsenical and bismuth was made on the same day, at weekly intervals. Since no greater percentage of complications was seen, this method has been in use for several years.

PREVIOUS TREATMENT

Approximately 30 per cent of our patients had received treatment prior to observation. Information relative thereto was frequently incomplete. In attempting to classify the previous treatment, we used the following criteria:

Poor (a) medication by mouth for a month or two, or less, (b) intragluteal treatment or injections only, or (c) less than one course of intravenous and intragluteal injections.

Fair (a) one course of intravenous and intragluteal injections, or (b) arsenical therapy, regardless of the amount.

Good two courses of intravenous and intragluteal injections.

Excellent three or more courses of intravenous and intragluteal injections.

TABLE 1—Treatment for Uncomplicated Late Syphilis

Weeks	Neoarsphen amine Cc	Bismuth Sal icylate Cc
1 to 10		10 weekly injections 0.5 to 2 cc
1 month's rest (optional)

If blood test is negative place on observation If positive give one course of bismuth each year

Iodides may be given throughout

This schedule is for a healthy adult male and the dosage of neoarsphenamine should be slightly smaller for women the bismuth dosage may remain the same

If blood test is negative place on observation. If positive give one course of bismuth each year.

Iodides may be given throughout.

This schedule is for a healthy adult male and the dosage of neoarsphenamine should be slightly smaller for women. The bismuth dosage may remain the same.

These criteria are based on the total amount of treatment previously received and not on the regularity and time intervals involved. Most of the previous treatment was not efficacious on account of long rest periods between courses. The treatment previously received was as follows: none in 131, poor in 10, fair in 33, good in 8 and excellent in 8. There were no data in 10 instances. This treatment was not considered in the evaluation of our own therapeutic results.

In our group of patients, initial examination revealed no diagnostic physical evidence of syphilis, although certain suggestive signs were occasionally found, such as irregular, unequal or sluggish pupils, abnormal knee jerks or an accentuated aortic second sound. Such suggestive signs were present also in some of the cases in the Cooperative Clinical Group report. Examination of the cerebrospinal fluid showed no abnormalities among 199 patients. One patient refused spinal puncture. There were roentgenograms or fluoroscopic examination of the cardiovascular stripe at various times during treatment in 21 per cent of cases. The duration of observation ranged from two to thirteen and one-half years. Approximately one half of the patients were observed for more than five years.

ANALYSIS OF RESULTS

In summarizing the final outcome of therapy we have generally utilized the Cooperative Clinical Group^{3b} terms and criteria. In those instances in which these terms are not applicable to our material or in which there was doubt in interpreting the criteria, we have defined our standards. The results of treatment in our series as compared with those of the total material of the Cooperative Clinical Group series is presented

TABLE 2—Results of Treatment of Latent Syphilis

	University of Chicago Clinics	Cooperative Clinical Group	
		Latent Cases	Late Latent Cases
Number of patients	200	1 013	1 107
Observation period	2 yrs or more	2 yrs or more	1 yr or more
Satisfactory results	68.5%	61.7%	33.7%
Clinical relapse	2.5%	4.6%	1.8%
Serologic relapse	3.0%	10.3%	11.3%
Serologic fast	26.0%	27.6%	31.3%
Still under treatment and doing well		0.3%	15.6%
Dead		1.4%	2.1%

in table 2, which includes data from tables XIII^{3b} and XIX^{3c} of the Cooperative Clinical Group. The final results are classified as follows:

Result satisfactory. No evidence of clinical progression or relapse. Physical examination and cerebrospinal fluid negative. Serologic test negative or doubtful (1 or 2 plus positive).

Clinical relapse or progression.

Serologic relapse. This classification includes patients who, after having been first observed with or having subsequently achieved a repeatedly negative or a 1 plus Kolmer or Kahn reaction as a result of treatment, later had a positive serologic reaction which was positive twice in succession. A repeatedly 1 plus reaction which changed to a repeatedly 3 plus reaction was classed as a relapse, a 2 plus reaction which changed to a 3 plus reaction was not considered a relapse.

Serologic fastness. All patients in whom the Kolmer or Kahn reaction was irreversibly positive (3 or 4 plus) after treatment.

In the Cooperative Clinical Group study the term "still under treatment" is used. Because of the relatively longer duration of our treatment and the fact that all our patients were observed for two or more years, this category is unnecessary in our analysis, since we have no comparable data. The final category "dead" has not been used in classifying our results. The reasons for this omission will be given.

In critical evaluation of table 2, the following facts should be borne in mind:

1. There are possible differences in interpreting the criteria used in defining the results.

2. The Cooperative Clinical Group study includes both early and late latency, our results are for late latent syphilis only.

3. The serologic tests used in the Cooperative Clinical Group study included various modifications of the Wassermann test, the Kahn and the Hinton flocculation tests. Hence many of the patients were subjected to a less sensitive test than others, which favorably influences the total results. Both the Kolmer complement-fixation and the Kahn flocculation test were routinely performed on each blood specimen reported by us, and a positive result of either test is recorded.

4. Table 2 records the final status at the end of the observation period. In both the Cooperative Clinical Group series and ours, a patient having a clinical or serologic relapse who subsequently received further treatment with satisfactory ultimate results is placed in the category of "result satisfactory." Such cases will be accounted for in our summary.

5. Six patients in our series are known to have died after observation periods ranging from two to twelve years. There was one accidental death, one suicide, one death from carcinoma of the stomach and one from carcinoma of the liver. The cause of death of 2 patients is not known, of whom 1 had an aortic aneurysm and was classified under "clinical relapse or progression." Since in no instance in our series was death known to have been caused by syphilis, the category "dead" is not used in our results.

The comparison of final results indicates that the most favorable outcome in most categories was obtained by our method of treatment. The use of percentages in a small number of patients at times gives high figures. The inference drawn from the Cooperative Clinical Group study that large amounts of heavy metal are more successful than arsphenamine in producing clinical and serologic negativity in latent syphilis seems to be verified by our report.

Our results are more significant when compared exclusively with cases of late latency from the Cooperative Clinical Group study. However, in this comparison, the Cooperative Clinical Group results are somewhat unfavorably influenced by the inclusion of some cases observed for less than two years.

Five cases are included in the category of "clinical relapse or progression." In 4 of these patients the following suggestive or diagnostic evidence of cardiovascular syphilis developed: in 1 aortitis, in 1 mild aortic insufficiency, in 1 aortic aneurysm and in 1 widening of the aortic arch (a woman aged 48). These cases may well represent clinical progression rather than relapse, since subclinical involvement of the aorta may have been present before the institution of therapy. In 1 case classified as a "relapse," retrobulbar neuritis and papillitis developed, which were not proved to be of syphilitic origin. In a sixth case which is not included as presenting a relapse in the final results, the initial cerebrospinal fluid examination was negative, with the exception of the colloidal gold reaction, which showed 1122100000. Subsequent examination revealed a positive spinal fluid Wassermann reaction, and a third specimen was reported negative.

Of the 6 patients with a "serologic relapse" at the time of the last observation, the Kolmer reaction became positive in 4 and the Kahn reaction in 2 instances. A total of 20 patients showed a serologic relapse at some

time during the period of observation. In this group there were thirteen Kolmer relapses, five Kahn relapses and 2 cases in which both tests showed a relapse. Although the term "serologic relapse" has been applied to these cases, we believe that there were actually few true relapses but rather that there was a vacillation in the quantity of reagent in the blood, which frequently occurs from time to time.

Of the 52 patients whose serologic test persisted as positive at the last observation, it is of interest to note the greater incidence of "Kahn-fastness" as compared with "Kolmer-fastness." In 19 instances both tests were "fast." Of the remainder, there were only 3 instances of "Kolmer-fastness" as compared with 30 of "Kahn-fastness." Thus measured by the Kolmer

those in the serologic fast category in table 2 is due to the recording of some Wassermann-fast cases in the more important classes of clinical or serologic relapse.

To illustrate the influence of large amounts of bismuth on the clinical outcome of therapy in which varying amounts of arsenicals are used, table 4, containing data from table XV of the Cooperative Clinical Group^{2b} report, is presented. In our series, much bismuth was given in addition to and also simultaneously with the specified amount of arsenical. The higher proportion of satisfactory results with our method is apparent when the two series are compared. The surprisingly high proportion of favorable results in the small group of patients who received little or no arsphenamine and much heavy metal in the Cooperative Clinical Group

TABLE 3—Results of Treatment in Latent Syphilis According to the Total Length of Observation

Thirty per cent of patients in the Cooperative Clinical Group had early latent syphilis.

test alone, only 11 per cent of our patients were Wassermann fast as compared with 26 per cent when both tests were employed.

In table 3 our treatment results, according to the total length of observation, are compared to similar data in table XVIII of the Cooperative Clinical Group^{3c} report. Both series show a greater proportion of satisfactory results as the duration of observation increased. However, the comparison indicates also that a higher percentage of favorable results was obtained within a two to five year interval by our method of therapy.

The relation of clinical outcome to the duration of observation may be shown also by a comparison of the serologic reactions that were obtained two years after the institution of treatment with the final serologic status. After two years a positive (3 plus or 4 plus) Kolmer reaction was present in 31 per cent of cases and a positive Kahn reaction in 40.5 per cent. These percentages had decreased at the final report to 14.5 per cent Kolmer positive and 27.5 per cent Kahn positive. The discrepancy between these percentages and

study is also confirmatory evidence of the efficacy of heavy metal therapy in latent syphilis.

In support of this finding, the results of treatment of 4 patients who received little or no arsenical and much heavy metal are analyzed. Two patients received no arsenical, 1 patient received one injection of thioarsene, and 1 patient received nine injections of bismarsen. One of these cases has been included in the previous gross material. The ages ranged from 47 to 64 years. Arsenicals were avoided in the treatment of these patients because of advanced age, hypertension or non-syphilitic cardiovascular disturbance. The dosage ranged from forty to eighty injections of bismuth. Satisfactory results with clinical quiescence and the reversal of the serologic reaction to negative were obtained in all cases.

COMPLICATIONS FROM THERAPY

An important advantage of the method of therapy used in our series has been the relative freedom from serious treatment complications, either from bismuth

or from the arsenical. By using combined treatment, i. e. bismuth and an arsenical simultaneously, a smaller dose of both drugs may be employed, thus reducing the toxicity without impairing the therapeutic efficiency. This observation was made by Schamberg⁴ and Wright⁵. The results of combined therapy in our clinic have led us to the same conclusion. Experimental confirmation of this statement is found in the study of Clausen, Langley and Tatum⁶. In working with experimental rabbit syphilis, they observed that the therapeutic effects of fractional doses of arsenicals and bismuth given together are mathematically additive, but the toxic effects are less than additive. Thus, the administration of 75 per cent of the minimal curative dose of an arsenical plus 25 per cent of the minimal curative dose of bismuth, or vice versa, will cure syphilis in rabbits. However, from 70 per cent to 90 per cent of the maximum tolerated dose of mapharsen plus 70 to 90 per cent of the maximum tolerated dose of bismuth, when given together, did not cause death. We have not noted any increase in complications from combined treatment over those reported for the alternating method. However, Wells and Sewell⁷ reported albumin and microscopically visible red blood cells and casts in the urines of patients being treated in the tropics with combined bismuth and arsenical medication. Neoarsphenamine alone or a bismuth preparation, bierecol, alone gave practically no untoward results. There was, however, no evidence of impaired renal function in any case. The authors believe that the profuse sweating in the tropics with associated small output of urine, which is concentrated, may result in toxic concentration of heavy metals in the convoluted tubules.

Since many of our patients received extremely large amounts of bismuth as compared to the total dosage usually given, the question of renal damage arises. One hundred patients received from forty to eighty injections of bismuth, 70 received eighty-one to one hundred injections and 30 received more than 100 injections. One patient who received bismuth therapy for lupus erythematoses subsequent to the completion of antisyphilitic treatment was given a total of one hundred and seventy-eight injections. Thus 10 to 15 Gm. or more of metallic bismuth equivalents were often administered. Periodic examinations of the urine were routinely performed on all patients. In 42 per cent of cases there were transient urinary changes, traces of albumin and small numbers of hyaline casts being the most frequent findings. Erythrocytes and cellular and granular casts were also reported occasionally. These urinary changes were often noted in patients with complicating conditions such as local pelvic disturbances, renovascular disease and pregnancy, so that the role of bismuth as the sole causative factor was often questionable. In no case was there evidence of serious renal damage from bismuth.

Stomatitis or gingivitis developed in 10 cases during bismuth therapy. This complication was controlled by

the proper dental and oral hygienic measures. Three patients complained of fatigue after an injection of bismuth, 2 noted anorexia. There was 1 instance each of dermatitis, chill, aching of the joints, stiffness of the hands and knees, and leg pain (neuritis?). Herpes zoster appeared in a few cases but was not necessarily considered a complication of bismuth therapy⁸. Bancroft⁹ found herpes zoster in 13 of 1,181 patients treated for syphilis at the Los Angeles Venereal Clinic. Eleven patients received both bismuth subsalicylate and neoarsphenamine, 2 received bismuth only. No relation to varicella, the virus of which is considered to be one cause of herpes zoster, was observed. He believes that bismuth may cause herpes zoster. It is also possible that some of the eruptions which originate in the lumbar region and progress downward were caused by trauma from injections into the buttocks. All complications occurring in our patients were controlled by the temporary employment of smaller doses of the drug or short rest periods from treatment. In a few cases the substitution of a product from a different pharmaceutical company was adequate. In no case was it necessary to abandon bismuth therapy permanently.

SUMMARY

The results of treatment of 200 patients with late latent syphilis by means of bismuth combined in part with an arsenical were compared with the results obtained by the Cooperative Clinical Group. The latter report includes both early and late latency, the dividing line being based on a duration of infection less than or greater than four years. All of our patients had had syphilis for three years and most of them for four years. They were observed for from two to thirteen and one-half years. Results presented in the Cooperative Clinical Group study suggested that maximum results are obtainable with about twenty injections of arsphenamine and large amounts of heavy metal, the latter given over long periods of time. The most favorable outcome in most categories was obtained by our method of treatment. The total amount and duration of bismuth therapy are greater in our method than in the Cooperative Clinical Group series. It is interesting to note that the one cooperating clinic which used relatively large amounts of heavy metal had the highest proportion of satisfactory clinical and serologic results in their series.

Complications from therapy by bismuth combined with an arsenical included transient urinary changes, stomatitis or gingivitis, fatigue, anorexia, dermatitis, chill, aching of the joints, stiffness of the hands and knees, leg pains and herpes zoster. All complications were controlled by the temporary employment of smaller doses of the drug or rest periods from treatment. In no case was it necessary to abandon bismuth therapy permanently.

Our impression that combined bismuth and arsenical therapy is superior to the same drugs used in alternating courses has been given experimental support by the work of Clausen, Langley and Tatum,⁶ who showed that the therapeutic effects of fractional doses of arsenicals and bismuth given together are mathematically additive, while the toxic effects are considerably less than additive.

BISMUTH HEPATITIS

A SURVEY OF ONE HUNDRED AND
TWENTY-ONE CASES

GEORGE V. KULCHAR, M.D.

SAN FRANCISCO

AND

WILLIAM J. REYNOLDS, M.D.

SAN ANSELMO, CALIF.

For many years extensive use has been made of bismuth compounds in the treatment of syphilis. Hepatitis due to bismuth, however, has only recently received general recognition. The failure to realize that hepatitis may result from the use of the drug is in a large measure due to the common tendency to attribute jaundice occurring during bismuth therapy to either relapse of the disease, intercurrent infection or previously received arsphenamine. Attention was first directed to bismuth as the cause of hepatitis by Langernon, Paget and Devriendt,¹ who in 1932 reported 13 cases in which jaundice was presumably due to bismuth. Langernon and his associates believed, however, that bismuth is not "hepatotoxic" in the sense that the arsphenamines are but that it has rather a nonspecific effect on the liver already damaged by syphilis, alcohol or previous arsenical therapy. The occasional occurrence of hepatitis presumably due to bismuth is likewise contained in reports primarily concerned with postarsphenamine jaundice.² A bismuth compound as interim heavy metal therapy is suggested by Soffer³ as being an important factor in the so-called late or delayed postarsphenamine jaundice.

Interest in bismuth hepatitis was stimulated by the report of 32 cases made by Nomland, Skolnik and McLellan⁴ in 1938. The following year in a survey of 100 cases of treatment jaundice Gott and Doyle⁵ believed that in 12 the hepatitis was attributable to bismuth. With the exception of Moore⁶ however, most textbooks do not mention bismuth hepatitis as a complication of treatment. The difficulties in determining whether the jaundice is due to bismuth, previous arsphenamine therapy or intercurrent infection are well described by Moore.

On the laboratory side there is some evidence that bismuth may damage the liver. In animals cloudy swelling and central necrosis may result from the injection of amounts larger than the usual therapeutic dose. In man a fatty infiltration of the liver was observed by Dowds⁷ in 3 fatalities due to sodium bismuth tartrate, while acute yellow atrophy attributable to the

drug has been reported by Albert,⁸ Juliusberg⁹ and Wollman.¹⁰ The fatalities, however, have for the most part followed the use of large amounts of soluble compounds or the intravenous injection of bismuth—circumstances which result in the rapid absorption of relatively large amounts. Determinations made by Sollmann, Cole and Henderson¹¹ and by Scholtz and Chaney¹² on the distribution of bismuth indicate that the liver ranks second only to the kidney in the amount contained. Severe anatomic damage, according to Sollmann and his co-workers, materially increases the concentration of bismuth, although minor changes or alterations had little effect on the amount contained. The significance of these observations in relation to bismuth hepatitis will be discussed subsequently.

Jaundice particularly during the bismuth phase of treatment, has been a frequent occurrence among the prisoners in the State Prison at San Quentin. Of the 1,032 inmates receiving treatment for syphilis between July 1, 1936 and Jan. 1, 1942, 144, or 13.9 per cent, became jaundiced one or more times during the course of treatment. In 121, or 10.3 per cent, of these the hepatitis occurred while bismuth was being given, the remainder receiving either an arsphenamine or tryparsamide at the time jaundice was first noted. As the latter was frequently given simultaneously with bismuth, it was usually impossible to determine which drug was responsible. These consequently are excluded from the present study, which is primarily concerned with bismuth hepatitis.

The treatment system consisted of neoarsphenamine or mapharsen in courses of ten weekly injections given in alternation with iodobismutol with saligenin in courses of twenty weekly injections. In patients with asymptomatic or clinical neurosyphilis, tryparsamide was frequently used in addition. Unless the infection could be established as less than four years in duration or treatment begun elsewhere was being continued, the initial course was routinely iodobismutol with saligenin. Except for interruptions due to reactions or intercurrent illnesses, treatment was received regularly, and in uncomplicated syphilis it was usually continued until the standard amount of thirty injections of an arsphenamine and sixty of iodobismutol with saligenin had been given, unless terminated by reason of transfer or parole.

Since the prison receives only male offenders females are not included in the present series. Of the 121 prisoners in whom jaundice first occurred during the bismuth phase of treatment, 103 were white and 18 were Negroes. The ages varied between 19 and 58, the average being 31.5 years. With the exception of primary syphilis in 2 inmates, all were in the latent stage or had later manifestations of syphilis at the time treatment was started. In 55 instances the duration of the infection was unknown, while in 12 it could be established as being less than one year and in 25 between one and four years in duration at the time treatment

was begun. Of the 121 prisoners with hepatitis due to bismuth 60 had received varying amounts of treatment prior to entry to the prison. None, however, gave a history of previous jaundice due to any cause. Except for gonorrhea in the history of 45 inmates, there were no predominantly common illnesses in the past.

Since jaundice due to either arsenicals or bismuth may occasionally remain undetected for several weeks there may at times be some difficulty in determining whether the hepatitis is due to the currently used or the previously received drug. Nomland and his co-workers excluded bismuth as the cause if jaundice appeared within twelve weeks of the last injection of an arsphenamine. Since jaundice at times occurs after only a few injections of bismuth in patients who have not received previous arsenical therapy or in patients after many months have elapsed since the last injection of an arsphenamine the twelve week criteria is not satisfactory applied to the continuous alternating system of treatment.

If recognition is given to a delayed hepatitis it is conceivable that jaundice occurring during the first few weeks of either bismuth or arsenical therapy may actually be due to the drug previously received. For these reasons we have in this study attributed the jaundice to the currently used preparation, realizing that at times the previous medication may have been at least in part responsible for the hepatitis.

Little information is available in the literature as to the incidence of hepatitis due to bismuth. Nomland, Skolnik and McLellan, on the basis of the twelve week criteria, reported the incidence to be 1 in 2,224 injections of bismuth salicylate. When the same criteria are applied for purposes of comparison only, the incidence of the complication following the 36,055 injections of iodobismutol with saligenin given during the period of this study is determined to be 1 in 1,030 injections, or more than twice that reported by Nomland and his associates.

Treatment was initiated with iodobismutol with saligenin in 82 of the 121 patients with jaundice due to bismuth. Of these, 4 became jaundiced during the first course of bismuth, previous arsenical therapy being excluded as the cause. The remaining 117 patients received arsenicals in some form prior to the bismuth course during which hepatitis occurred. The onset of jaundice was noted within four weeks of the last injection of an arsenical in 34 cases, and in some this rather than the bismuth may have been responsible. Evidence of hepatitis did not appear until four or more weekly injections of bismuth had been given in 83 and not until after eight or more weekly injections in 56 cases. The time intervening since the last injection of an arsenical in these makes it unlikely that the hepatitis is entirely due to previous arsenical therapy. The occurrence of jaundice during the first course of heavy metal in only 4 of the 82 cases in which treatment was initiated with bismuth when compared to the 117 cases in which arsenicals were given prior to the bismuth course during which hepatitis occurred indicates that previous arsenical therapy may be a factor.

Chart 1 — Comparison of the incidence of hepatitis during initial course of bismuth with and without preceding arsphenamine. Black column iodobismutol only; hatched column iodobismutol preceded by arsphenamine.

As may be expected, the incidence of bismuth hepatitis is influenced by the duration of antisyphilitic treatment. This is not, however, proportional to the amount of arsphenamine previously received. Of the 121 patients, 81 received 4.5 Gm or less of neoarsphenamine (for equivalent amounts of mapharsen) prior to the bismuth course during which jaundice occurred, 30 received more than this amount. In 6 cases of hepatitis due to bismuth only tryparsamide had been given previously.

The treatment of 33 of the 121 patients with bismuth hepatitis was initiated with an arsphenamine. Of these patients 25 became jaundiced during the first course of bismuth. The influence of previous arsphenamine therapy on the incidence of bismuth hepatitis is shown graphically in chart 1.

Chart 1 indicates that only 4.8 per cent of the patients became jaundiced during the initial course when treatment was begun with the heavy metal as compared to the 75.7 per cent during the first course of bismuth when treatment was initiated with an arsphenamine. Previous arsphenamine therapy would seem to be a factor of considerable importance in predisposing to hepatitis from the use of bismuth.

As may be expected, the incidence of bismuth hepatitis is influenced by the duration of antisyphilitic treatment. Of the 121 patients, 25 became jaundiced during the first six months of treatment as compared to 75 during the second six months of therapy. During the second year hepatitis occurred in 21 patients, the decrease being due largely to termination of treatment as adequate or by reason of transfer or parole during this period.

A parallel between the incidence of postarsphenamine jaundice and catarrhal jaundice has been reported by Stokes, Reudemann and Lemon,¹³ by Ruge and by Todd.¹⁴ There have, however, been no epidemics of catarrhal jaundice among the prisoners during the period covered by this study. Neither has catarrhal jaundice been endemic, the incidence among the prisoners during 1941 being 0.1 per cent. During the same period among prisoners receiving bismuth the incidence of hepatitis was 10.3 per cent, or one hundred times greater. There has been no simultaneous increase in the incidence of postarsphenamine jaundice. On the basis of the criteria previously discussed, the incidence of postarsphenamine jaundice for the same period is 1 in 937 injections, or slightly greater than that of 1 in 998 injections reported by the Cooperative Clinical Group.¹⁵

The number of patients with bismuth hepatitis did not vary greatly from year to year, the smallest being 22 in 1938 and the largest 35 in 1941. Similarly, there was no great monthly variation, the largest number of cases in any one calendar month being 7. Taking the aggregate of the years, 66, or 54.5 per cent, of the cases occurred during the winter months (October to March) while 55, or 45.5 per cent, occurred during the spring and summer (April to September). Similar seasonal increases for postarsphenamine jaundice have been reported by Ruge, by Stokes, Reudemann and

Lemon and by Wile and Sams¹⁶ Stokes and his associates attributed the increase to the prevalence of infections of the upper respiratory tract during the winter months. While respiratory infections are common among the prisoners during the winter months the slight increase in the number of patients with bismuth hepatitis during these months would indicate that such infections are at least not a major factor.

Chart 2—Symptoms and signs among 121 patients with hepatitis due to bismuth

Bismuth hepatitis like postarsphenamine jaundice, is frequently difficult to distinguish from catarrhal jaundice. The difficulties in differentiation are well summarized by Moore. Among the 121 patients with hepatitis due to bismuth all degrees in the severity of symptoms and the intensity of the jaundice were observed. For the most part, however, the symptoms were not sufficiently severe to require hospitalization, and the prisoners continued their usual duties. Data as to the symptoms and signs available in 51 cases are summarized in chart 2. The symptoms grouped under the term nausea and vomiting varied from anorexia and aversion to food to actual nausea and vomiting.

The duration of jaundice could be determined in 113 cases. In 3 the symptoms and icterus disappeared in less than two weeks while in 34 recovery was complete in from two to four weeks. The jaundice in 39 persisted for from four to six weeks and from six to eight weeks in 29 cases. In all but 8 the jaundice had disappeared by the end of eight weeks, the longest period being twelve weeks in 1 case.

Treatment was subsequently continued in 107 of the 121 cases of bismuth hepatitis. In 9, or 8.4 per cent, there was a recurrence of the jaundice. This occurred during bismuth therapy in 4 and while arsphenamine was being given in another 4. Jaundice recurred with trypanamide in 1 case.

The frequency with which hepatitis was encountered as a reaction to treatment cannot be attributed solely to the iodobismutol with saligenin. In the experience of others hepatitis due to iodobismutol with saligenin has not been reported.¹⁷ Only 1 instance of hepatitis has been noted following more than 80,000 injections of this drug given in the Syphilis Clinic of the Stanford University Hospitals.

Damage to the liver by alcohol is suggested by Langeron and his co-workers as a predisposing factor

in bismuth hepatitis. Using information given by the prisoners, the past record of arrests for drunkenness and the impressions of the prison psychiatrists made at the time of entry, we made an attempt to determine the amount of alcohol used in the past taking as a control group 200 prisoners receiving antisyphilitic treatment without hepatitis as a reaction. Among those with bismuth hepatitis 18.1 per cent used no alcohol, approximately the same proportion, 22 per cent, as in the control group. Moderate amounts were used by 26.3 per cent of those with hepatitis as compared with 44 per cent among the controls. Of the prisoners with hepatitis, 55.5 per cent used excessive amounts while only 22 per cent of the control group were chronic alcoholic addicts. While the rigidity of the criteria may well be questioned it would seem that previous hepatic damage due to alcohol may predispose the liver to further injury by bismuth.

The effect of diet in protecting the liver against injury by drugs, particularly the arsphenamines, has been the subject of much controversial discussion. The more recent studies made by Messinger and Hawkins¹⁸ and by Miller, Ross and Whipple¹⁹ indicate that a greater protective effect is afforded by the protein fraction than by either the carbohydrate or the fat. Vitamin B complex, or at least certain fractions of it, may also have, according to recent studies, some effect in protecting the liver from injury. For these reasons an analysis of the diet for a ten day period was made. Since the prisoners are fed in a common mess quantitative measurement of the food taken could not be obtained, and for purposes of calculation the normal intake of between 2,600 and 3,000 calories daily was assumed. The results of the analysis are given in the accompanying table. The minimum standards adopted by the Foods and Nutrition Board of the National Research Council²⁰ are given for comparison.

The comparison made in the table shows the diet to be fairly adequate. The amount of protein, while not high, is above the minimum requirements. The vitamin B complex, particularly the riboflavin, is, however, somewhat less than the recommended amount.

Comparison of Average Diet Received by Prisoners with Standards Recommended by the Food and Nutrition Board of the National Research Council

	Carbohydrates Gm	Protein Gm	Fat Gm	Calcium Gm	Iron Mg	Vitamin A, Inter- national Units	Thiamine Hydro- chloride (B ₁) Mg	Ascorbic Acid (C) Mg	Riboflavin, Mg
San Quentin Standard	381 70	90 70	79 0.5	0.75 0.8	15 12	5,729 5,000	13 1.8	61 75	1.47 2.7

Pending further studies on the protective effect of vitamin B complex, the significance of deficiency in relation to treatment jaundice cannot be determined. Changes in the liver have been observed in diets deficient in vitamin B complex. Fatty infiltration of the

liver has been reported in animals on a riboflavin deficient diet by Sebrell and Onstott,²¹ while Von Glahn and Flinn²² found that cirrhosis of the liver produced by lead arsenate could be regularly prevented by the addition of yeast to the diet. The studies made by Forbes and his co-workers²³ and by Drill and Hays²⁴ have given further evidence that vitamin B complex may have some protective effect on the liver. Certain types of toxic hepatitis and cirrhosis, according to Gyorgy and Goldblatt,²⁵ may be due to a deficiency of vitamin B complex. The assignment of any major role to vitamin B complex in treatment jaundice, however, must await the results of further study. Similar deficiencies must certainly exist, particularly in clinic practice where treatment jaundice is a relatively infrequent complication.

The precise causation of bismuth hepatitis, like that of postarsphenamine jaundice, is as yet undetermined. In the latter, according to Moore,²⁶ a number of factors including the diet, damage to the liver by syphilis and the strain of metabolizing arsphenamine are involved. It seems probable that on this background of hepatic damage there is superimposed an infection the exact nature of which is as yet unknown. To this concept Sager² subscribes, stressing the frequent association of treatment jaundice with infections of the respiratory and the gastrointestinal tract. The association of post-arsphenamine jaundice with epidemics of catarrhal jaundice led Stokes, Reudemann and Lemon to believe that the two were due to the same infection. Muller²⁸ and Zimmern,²⁹ however, were unable to show any correlation between the incidence of postarsphenamine and catarrhal jaundice. Sager, after reviewing the literature, concluded that while the two may act in summation or potentiation, the evidence was preponderantly in favor of their separate identity. While the source and nature of the infection is as yet undetermined, it may be significant that the highest incidence of treatment jaundice has been reported from military services where men live in close association, increasing the opportunity for transmission of infection.

The concept of treatment jaundice as a summation effect resulting from the interaction of several or more factors, which independently are insufficient to cause the clinical manifestations of hepatitis (Sager) may well be the explanation for the frequent occurrence of jaundice due to bismuth reported here. It is difficult, however, to evaluate even in a general way the relative importance of the various factors. While damage to the liver by arsphenamine, alcohol and deficiencies in the diet may be contributory, the fact that the clinical manifestations of hepatitis occur during the period that bismuth is being received indicates that the heavy metal is the primary factor.

SUMMARY

The occurrence of hepatitis due to bismuth in 121 patients receiving treatment for syphilis has been determined to be 103 per cent, with recurrence of the hepatitis on continuation of treatment in 84 per cent. The effect of previous arsphenamine therapy as well as the less evident factors of diet, alcoholism and intercurrent infection all predispose the liver to damage from bismuth.

Bismuth hepatitis like postarsphenamine jaundice, is due to a summation effect resulting from the interaction of several more factors which individually are insufficient to cause the clinical manifestations of hepatitis.

While the importance of predisposing factors cannot be denied, the primary cause would seem to be the bismuth itself.

450 Sutter Street

ABSTRACT OF DISCUSSION

ON PAIERS OF DR. BEERMAN, SHAFFER AND LIVINGOOD,
DR. KAHN AND BECKER AND DR. KULLIAR
AND REYNOLDS

DR. FRANK C. COMBES, New York. My experience with bismuth has been very sparse in the last few years. Previous to 1932 I used large amounts of it but I developed an aversion to all preparations containing the sulfonate radical. Until now I have always considered that a proper evaluation of this drug as an antisyphilitic agent had never been determined. What are the basic requirements of a drug offered for the treatment of syphilis? It must be lethal to the invading organism. Bismuth, although not as active as arsphenamine has a definite beneficial effect in early syphilis. Second, it must be relatively nontoxic to the host. Serious sequelae to injections of bismuth are few. Ruiz and Severin determined that the maximum tolerated intravenous dose is twenty times the curative dose in syphilitic rabbits. However, I do not think that the purpose of Dr. Beerman and his co-workers was to offer a universal substitute for arsphenamine, because no arsenical which has been advanced or suggested has the activity of arsphenamine and I regret to hear that one of our largest pharmaceutical manufacturing houses is discontinuing its manufacture. But in bismuth we have a valuable addition which is applicable to those patients for whom intravenous therapy is untenable or impossible such as prenatal syphilis and to those patients who react unfavorably to other arsenicals to a select group of cardiovascular patients, in early neurosyphilis, in some instances of Wassermann fastness and for the use of those physicians who are unable to perfect themselves in intravenous medication. This latter may seem like a minor requirement but we are in need of an intramuscular arsphenamine, and I trust that in the next paper to be read that requirement may be answered.

DR. C. J. LUNSFORD, Oakland, Calif. The findings presented by Drs. Kahn and Becker indicate that, in those cases of syphilis which are least likely to withstand successfully the action of the more toxic drugs, excellent results can be obtained by more conservative methods of treatment. During the last several years in our office we have had patients with late and latent syphilis who were sensitive to arsenic. For some we have used no drug other than bismuth and have observed complete disappearance of cutaneous lesions and a reversal of their positive Wassermann reactions. It therefore did not surprise us to learn of Drs. Kahn and Becker's excellent results obtained by combining little arsenic with much bismuth in the treatment of late latent syphilis. Now comparing the results obtained by the Oakland Health Center in the two to five year group with those of the University of Chicago and the Combined Clinic Group as illustrated in the paper by Drs. Kahn and Becker it is seen that the Oakland Health Center obtained 50 per cent satisfactory results, the University

of Chicago 67.3 per cent satisfactory results and the Combined Clinic Group 46.1 per cent satisfactory results. In the two to five year group the University of Chicago obtained definitely better results than did either the Combined Clinic Group or the Oakland Health Center. As the Oakland Health Center patients received exactly the same amount of arsphenamine and about the same amount of bismuth as did the patients of Drs. Kahn and Becker, the question naturally arises: Why the difference in results? It would seem likely that the rest periods given in the treatment by Drs. Kahn and Becker do not account for the favorable results which they obtained, because the Combined Clinic Group studies of late latent syphilis showed that the little difference observed in the results obtained by continuous treatment compared to the interrupted treatment procedure favored the continuous treatment method. Drs. Kahn and Becker state that their patients cooperated in that they received their treatment regularly. The patients treated at the Oakland Health Center are on the whole unreliable, and the majority did not receive regular treatment. Combined Clinic Group studies showed that in the treatment of early syphilis irregular treatment was worse than no treatment at all. Reasoning by analogy, this difference in cooperation could well account for the superiority of Drs. Kahn and Becker's results as compared with those reported by me.

DR H. C. SAUNDERS, New York. I agree with most of the conclusions of Drs. Kahn and Becker. There is no doubt that bismuth has rightfully replaced mercury to a great degree in the treatment of syphilis. Bismuth alone should not be relied on to cure syphilis in the earlier stages. This practice cannot be too emphatically condemned. As the disease progresses, however, bismuth becomes more and more important and the trivalent arsenicals less and less so. In the later stages of the disease there are many patients whose only medication should be bismuth. This seems to be borne out by the figures in table 4. The groups receiving less than twenty injections of an arsenical show a higher percentage of satisfactory results and, with the exception of the clinical relapses, lower percentages of untoward results than those groups receiving more of the arsenicals. This is also true in the report of the Combined Clinic Group. I agree with them in their choice of arsenicals. In latency we do not need the greater potency of arsphenamine but rather the milder action of neoarsphenamine or mapharsen. There can be no question as to the advisability of treating latent syphilis. In addition to the points made by the authors, the possibilities of serious relapse or death is reduced from 25 to 30 per cent to about 5 per cent by such treatment. In late latency the problem of choice of preparations, of their dosage and of the amount of treatment must be dictated more and more by the individual requirements, i. e., while we can in earlier syphilis have a set routine for practically all patients, in latency a set formula becomes less and less useful and the individual needs more and more important. Of all the preparations listed by the Council, I believe that bismuth subsalicylate is the most valuable, especially if suspended in peanut oil. I do not believe that a greater dosage of bismuth is necessary than will maintain a daily excretion in the urine of from 2 to 4 mg. of elemental bismuth or that it will be productive of better results. I am glad to note that the authors set a minimum of twenty-four doses of an arsenical divided into three courses. This more than fulfills the requirement set forth by the Combined Clinic Group which showed that 72 per cent of all relapses occurred in patients receiving less than twenty injections of an arsenical. In evaluating the previous treatment I believe the authors have been rather optimistic. I should be inclined to place most of those in the first two groups as being very poor. This, however, does not detract from the result obtained but tends rather to enhance its value.

DR JOHN ERIC DALTON, Indianapolis. The role which bismuth alone may play in this complex problem of therapeutic hepatitis is somewhat debatable. We are all willing to admit that it may be the agent which comes along to produce a break in a hepatic resistance, which has been previously deeply undermined by the syphilitic infection itself, previously administered arsenical therapy, intercurrent infections, alcoholism, dietary

deficiencies, and the general wear and tear of life on this organ. Thus it would still seem controversial that bismuth, when administered singly and in doses of proper therapeutic size, can produce severe liver changes when its administration has not been preceded by other factors which have lowered hepatic efficiency. Cole and Sollmann showed that, when severe anatomic changes occur in the liver, the amount of bismuth held by this organ is materially increased, and we can see that under those conditions bismuth could lead to further grave alterations. The 3 cases described by Dowds scarcely come into the realm of a study on therapeutic jaundice, because in all those cases the doses which were employed were far higher than those used in carefully managed treatment. One does not deny that massive doses of the drug can produce severe or fatal liver damage, because this has been amply demonstrated in animal experiments. Further, the case cited from Wollman in which a fatal outcome occurred in a 1 month old infant following a single dose of bismuth is open to question. He records that the mother of this child was treated during her pregnancy, and it is most likely that she received an arsenical which the infant was subjected to transplacentally. Also it seems illogical that a single properly sized intramuscular dose could have produced all the changes which led to death in the short space of three days. Again it seems strange that after an interim bismuth therapy can be resumed without ill effect in many of these cases which have previously shown signs. It is noted that there was a recurrence of the jaundice in 9 cases in this report, but in 5 of those it happened when an arsenical was being administered. When we compare the greater incidence of this manifestation in individuals living in close contact as against its lesser occurrence in clinic practice, we are almost forced to consider some other interplaying factor, which might well be an intercurrent infection. There may be considerable yet unrevealed light in the studies which are in progress dealing with the interaction of diet and the patient's behavior to metals and in particular those experiments which Gyorgy is doing in relation to the deficiency in a constituent or constituents of the vitamin B complex.

DR BERNARD APPEL, Lynn, Mass. My experience with bismarsen in the Boston City Hospital, with about 25,000 syphilitic visits a year, and in a smaller clinic with about 10,000 syphilitic visits a year, at the Lynn Hospital, has gradually led me to rely on bismarsen principally in cases in which the intravenous use of a standard arsphenamine is contraindicated and principally when there are technical difficulties by the administering technician. I should like to differ with Dr. Beerman and his co-workers in their statement about bismarsen in cardiovascular syphilis. When we have a drug like mapharsen, which has been shown to be almost entirely free from nitritoid reaction, which is the most serious one that we can possibly have in these cases, and when we further know that bismarsen is capable of producing nitritoid reaction, we might be justified in thinking that bismarsen should not be the drug of choice in cardiovascular syphilis. As far as other reactions are concerned, I have seen a number of instances in which reactions of one sort or another toward treatment with the standard arsphenamine has been followed later by similar, identical although somewhat milder reactions when bismarsen was used in that same case. As for the paper of Drs. Kulchar and Reynolds, when we hear a statement which is in sudden conflict with what has been commonly accepted for a long time as a fundamental, the usual reaction is controversial. Such is likely to be our reaction to this paper. The authors have tempered their remarks continually by obviously direct or implied admissions of the controversial aspect of the principal theme. They have presented, however, out of the total of 121 patients, only 4 who became jaundiced during the first course of bismuth in whom previous arsenical therapy can be excluded. If, however, we consider other reports in the literature of cases of jaundice following injections of bismuth only, we are then confronted by a slowing accumulating group of observations from which we may reasonably conclude that intramuscular injections of bismuth, especially the water soluble compounds, may seriously damage the liver. So far, however, all the evidence points to a relatively low incidence of this complication.

The high incidence of nausea, vomiting and epigastric discomfort present in these cases of jaundice point quite definitely to a transient injury to the liver as a cause

DR HERMAN BEERMAN, Philadelphia I have little to say except thanks to Dr Combes and Dr Appel and to Dr Combes particularly because of his considered opinion in analyzing the material which we have presented Unfortunately the fourteen year observation period of the drug was not commented on This was the major object in presenting this paper, not the discussion of the merits or demerits of bismarsen With regard to the use of bismarsen in cardiovascular syphilis, we felt that it was advisable, largely on the recommendation of cardiologists, to use an intramuscular preparation such as bismarsen in preference to an intravenous preparation There is, however, some evidence to indicate that other drugs usually administered intravenously, mapharsen, for example, may be used intramuscularly While there are other drugs for cardiovascular syphilis, the route of administration of the preparation is extremely important

DR S WILLIAM BECKER, Chicago I think, as Dr Lunsford suggested, that the regularity of treatment as carried out by our patients may have made the difference between our results and the results in the more or less charity clinic I am sorry that we did not carry out urinary excretion studies I should like to state too that the combined treatment by means of bismuth and an arsenical is also efficacious in early syphilis I should like to take exception to a statement made by Dr Stokes earlier in the morning that we should wait a year before we supply boards of health with standard systems We have the same situation as the man who has never purchased a radio because he wants to wait until they are perfected We never attain perfection We have here the combined systems Bismuth and an arsenical have given us the maximum clinical and serologic results with a minimum of complications, and this idea has been fortified by experimental studies Our systems of therapy not only tell the physician how to start treatment but also tell him how to stop treatment, a feature which has been neglected in most systems of therapy There is a gratifying tendency to combine bismuth with the arsenical in the various systems of treatment now in use elsewhere In the studies on the five day intensive method for early syphilis some clinicians are now combining bismuth with the arsenical The combined courses should give us a superior therapeutic index

DR GEORGE V KULCHAR, San Francisco From the outset I realized that the concept that hepatitis may result from the use of bismuth might be critically discussed, particularly in view of the frequency with which it was encountered among our patients If one regards hepatitis as a progressive affair with variable degrees of severity ranging from simple toxic hepatitis to acute yellow atrophy, the citation of acute yellow atrophy from the use of bismuth with which Dr Dalton took exception seems reasonable His exception is well taken, however, as they are rare and severe injuries as a result of the rapid absorption of large amounts of bismuth and do not represent the chronic hepatic injury which results from the continued use of bismuth They are rather similar to the acute yellow atrophy that results occasionally from the use of other drugs

The Negro as a Surgical Risk—Surgeons who have had considerable clinical experience with Negroes commend them as excellent surgical risks They are stoic in their reaction to pain and discomfort, do not easily go into shock, take anesthesia well, resist infection, and show remarkable powers for recovery Most colored people live strenuously, a reflection of which is in the many severe injuries they receive either as accidental industrial injuries or as the result of altercations Some of these injuries are so serious as to merit an almost hopeless prognosis Yet many times they recover with ease and with remarkably little disablement The first person to undergo a successful cardiac suture was a Negro, which was as much a tribute to the hardihood of the patient as it was to the skill of the surgeon, who, incidentally, was himself a Negro—the late Dr Daniel H Williams—Lewis, Julian H The Biology of the Negro, Chicago University of Chicago Press 1942

MASSIVE HEMORRHAGE INTO
BRAIN TUMOR

ITS SIGNIFICANCE AND PROBABLE RELATIONSHIP
TO RAPIDLY FATAL TERMINATION AND
ANTECEDENT TRAUMA

JOSEPH H GLOBUS, M D
AND
MILTON SAPIRSTEIN, M D
NEW YORK

The opinion is often expressed that massive hemorrhage into a brain tumor is responsible for an abrupt change in the intracranial contents resulting in a rapid fatal termination It is also postulated, and often claimed, that such massive hemorrhage into a brain tumor may be caused by violence to the head We are unaware of any satisfactory proof which is based on a sufficiently representative number of verified cases of brain tumor, that has yet been offered to support these two views Moreover, the large material of Cushing, which was analyzed by Oldberg,¹ led the latter to

TABLE 1—Ninety Four Cases of Unoperated Brain Tumor in Which the Cause of Death Was Due to Brain Tumor

conclude that hemorrhage into brain tumor plays an unimportant role in the clinical picture, while elsewhere we² have corroborated the observations of Kernohan and Parker³ that the causative relationship between trauma and brain tumor in general has been overemphasized if it exists at all

With this in mind, we undertook a survey of a large number of primary and secondary, clinically and anatomically observed brain tumors to study the influence of hemorrhage into a brain tumor on the subsequent anatomic and clinical events and either to establish or to exclude a probable relationship between trauma and hemorrhage into a brain tumor

THE MATERIAL AND METHODS

The anatomic findings and the clinical histories of 370 cases of brain tumor were available, but only 94 were used for this study (table 1) These were selected

From the Laboratory and the Neurological Service of the Mount Sinai Hospital New York
Read before the Section on Nervous and Mental Diseases at the Ninety Third Annual Session of the American Medical Association Atlantic City N J June 11, 1942

because they were not subjected to surgical intervention, and thus confusion which might have arisen from the question as to whether intracranial surgery might have acted as a traumatizing agent was obviated.

In analyzing our material it was necessary to evaluate three variables which may be encountered in the history

Fig 1—A thrombosed blood vessel with an area of softened brain tissue around it

of a brain tumor (1) massive and explosive hemorrhage into the tumor, (2) sudden and abrupt change in the clinical picture leading to a rapidly fatal termination and (3) violence to the head occurring at some period in the history of the host of the tumor. The pathologic alterations were at first studied independently of, and without any recourse to, the available clinical information and then correlated with the latter.

DEFINITIONS

1 *Massive Hemorrhage into Brain Tumor*—A more rigid definition is to be adopted for the term "hemorrhage into brain tumor" before its significance can be

numerous and that many of them show alterations which frequently result in their complete closure. These changes in turn result in necrosis of the tumor tissue about such blood vessels (fig 1). Both circumstances, the alterations in the vessel wall and the necrotic changes in the neighboring tumor tissue, invite migration of blood elements by diapedesis and their dissemination throughout the surrounding tissue (fig 2). Such seepage of blood, as well as decided vascularity of the tumor (fig 3), often gives rise to gross discoloration of the tumor tissue suggesting hemorrhage into the neoplasm (fig 4). Such passage of blood elements into surrounding tissue which may be designated as extravasation in contradistinction to hemorrhage, a more formidable and active escape of blood from blood vessels, is a common occurrence. While this form of seepage may contribute toward the sum total of the clinical manifestations, it need not be regarded as constituting a critical and certainly does not in addition serve as an abrupt event in the anatomic behavior of the tumor or the clinical course.

TABLE 2—Nine Cases of Hemorrhage into Brain Tumor

Case	Diagnosis	Site	Type of Death	Blood in Cerebrospinal Fluid	Trauma

8	Neurospongioneuroblastoma	Right temporal	A	No	No
9	Metastatic lung	Left frontoparietal	C	No	No

A Sudden death in instances in which symptoms of brain tumor developed without significant prodromal symptoms

B Sudden death in cases in which brain tumor was diagnosed

C Gradual decline leading to death in cases diagnosed as brain tumor

There are, however, occasional instances in which there is an explosive and massive escape of blood into the tumor or the adjacent tissue. True hemorrhage is an extensive phenomenon, with the blood accumulating in a solid mass beyond the confines of the ruptured blood channels (figs 5, 6 and 7). The voluminous character and the explosive nature of such hemorrhage is believed to be capable of causing an abrupt and commonly a fatal change in the clinical course. It is this type of hemorrhage that drew our particular attention.

Peculiarly enough, and against the commonly accepted views, we found such hemorrhage into a tumor in only 9 cases out of the total of 94 (table 2). Of these 9 cases, 4 were of the malignant neuroectodermal variety designated as spongioneuroblastoma or spongioneuroblastoma, 1 was a less malignant type of glioma, the so-called transitional glioma, 1 was a hemangioma, and 3 were (secondary) metastatic tumors.

In 7 instances there were linear extravasations of blood into the brain stem distal to the site of the tumor. In only 1 case were linear hemorrhages found in the brain stem, accompanying massive hemorrhage into a brain tumor.

Fig 2—A thickened blood vessel with extravasation around it.

properly evaluated. The experience of those who have studied large brain tumor material reveals the fact that it is the exception rather than the rule for a tumor not to show some seepage of blood from its blood vessels into the surrounding tumor tissue. This phenomenon is readily understood when it is recognized that in the majority of instances of brain tumor the vessels are

2 Sudden and Abrupt Change in the Clinical Picture—Since the immediate clinical evidence of the effect of trauma or the changes which are assumedly provoked by hemorrhage into the tumor can be gaged only by objective neuropsychiatric findings, the need for criteria

Fig. 3—An extremely vascular area in the brain tumor shown in figure 4

as to what constitutes a sudden alteration in the clinical picture is quite obvious. Accordingly two clinical syndromes should be considered. One characterizes a patient who, at first apparently well with or without minor complaints of a neurologic character, suddenly collapses and develops stupor which deepens progressively and terminates in less than twenty-four hours

Fig. 4—An extremely vascular tumor of the brain (spongioblastoma multiforme)

in death. There were 15 such cases. A second clinical syndrome typifies a more commonly encountered situation in which the patient who has been under investigation for some time with a brain tumor strongly suspected or definitely established suddenly passes into stupor, declines rapidly and without regaining consciousness

dies within a few hours (at the most forty-eight hours). Twenty-six of our patients died in this fashion. In a third category, the largest in our material, there are 53 cases in which the clinical course is marked by gradual decline terminating fatally.

3 Violence to the Head in Verified Cases of Brain Tumors—In a previous communication we² have classified head trauma in accordance with the severity of the violence and have defined several categories. Thus, there are instances in which the history records slight violence to the head without immediate untoward manifestations, such as clouding or loss of consciousness, headache or any other neurologic sign and symptom. Such cases are designated 1 plus or 2 plus. In a second group there are cases, designated 3 plus in which the injury was followed by a brief period of unconsciousness without subsequent clinical manifestations including headache. In still another group there are cases designated 4 plus in which the trauma was of such severity

Fig. 5—A massive hemorrhage into a brain tumor

that it was accompanied by a relatively long period of unconsciousness (one-half hour or more) and followed by recurrent headache. In the material of the present investigation there was a total of 16 cases in which there was a history of head trauma. Four of these belong in the group of 3 plus and 4 plus. In only 1 of these cases did the trauma occur shortly before the onset of the symptoms, the tumor was a spongioblastoma, in another case the trauma was said to have occurred two years before the onset of signs of neurologic disturbance, in a third case the trauma was recorded as having occurred six years prior to the development of neurologic complaints, and in the fourth case the trauma occurred one month after the onset of signs of brain tumor.

SUMMARY OF OBSERVATIONS

1 Sudden Death in Relation to Hemorrhage into Brain Tumor—Fifteen out of our series of 94 patients died suddenly and unexpectedly (table 3). Of these, only 1 disclosed a hemorrhage into the tumor. This

patient also had a linear extravasation into the brain stem. One other patient who died suddenly had a similar brain stem lesion without hemorrhage into the tumor. Of the remaining 79 patients of our series who declined more gradually, 8 had hemorrhage into the tumor with additional extravasations into the brain stem in 5 cases. It would seem that hemorrhage into a brain tumor is not a determining factor in the production of sudden death.

2 Sudden Death in Its Relation to Head Trauma in Patients with Brain Tumor—None of the patients who died suddenly had suffered any trauma to the head.

TABLE 3—Fifteen Cases of Brain Tumor with Sudden Death

Case	Diagnosis	Site	Hemorrhage into Tumor	Blood in Cerebrospinal Fluid After Onset of Acute Symptoms	Trauma	Duration of Terminal Clinical Phase	Vascular Lesion in Brain Stem
1	Medullo-blastoma	4th ventricle	No	No	No	15 min	No
2	Spongioblastoma	3d ventricle	No	No	No	40 min	No
3	Glioma	Left hemisphere	No	No	No	30 min	No
4	Metastatic	Pons and 4th ventricle	No	Yes	No	5 hrs	Yes
5	Metastatic	Right pontofacial angle	No	No (before onset)	No	6 min	No
6	Spongioblastoma multiforme	Right temporal	No	No	No	24 hrs	No
7	Spongioblastoma multiforme	Interfrontal	No	No (before onset)	No	1 hr	No
8	Spongioblastoma multiforme	Right hemisphere	No	Yes	No	12 hrs	No
9	Meningioma	Left temporo-parietal	No	No	No	24 hrs	No
10	Ependymoma	Right lateral ventricle	No	Xanthochromic fluid	No	24 hrs	No
11	Metastatic	Right cerebellar	No	No (before onset)	No	30 min	No
12	Cranio-pharyngealoma	3d ventricle	No	No (before onset)	No	10 min	No
13	Neuroglioma	Left frontoparieto-temporal	No	No	No	40 min	No
14	Spongioblastoma	Right temporal	Yes	No (before onset)	No	10 min	Yes
15	Spongioblastoma	Left thalamus and midbrain	No	No	No	2 hrs	No

Sixteen patients gave a history of some form of head trauma but none of these died suddenly. In 4 cases the trauma was severe enough to cause loss of consciousness, but in only 2 did the injury occur during the course of the brain tumor.

3 Sudden Death in Instances of Brain Tumor with Evidence of Bleeding Found in the Cerebrospinal Fluid—Ten patients who died suddenly had been subjected to lumbar puncture. Three showed some evidence of bleeding (red blood corpuscles in the cerebrospinal fluid or xanthochromic fluid). Of those (79 patients) who died less abruptly, 59 had been subjected to this procedure and 18 showed evidence of blood in the cerebrospinal fluid. It cannot be said, therefore, that blood seepage into the cerebrospinal fluid is associated with sudden death.

4 Sudden Death in Relation to the Histologic Type of Brain Tumor—No specific type of tumor showed a statistically higher percentage of sudden death. Fifteen such deaths were distributed among 7 divergent forms of tumor (table 1).

Fig 6—Hemorrhage area under high magnification

5 Sudden Death in Relation to the Site of Brain Tumor—Of the 15 patients who died suddenly, 7 had involvement of the third ventricle and infratentorial regions. In 8 involvement was restricted to the cerebral hemispheres, with varying localization (table 2).

6 Hemorrhage into Brain Tumor in Its Relation to Head Trauma—While 9 patients had had hemorrhage into the tumor and 16 patients gave a history of head trauma, in only 2 instances was there some association

Fig 7—Microscopic appearance of massive hemorrhage into a brain tumor showing sharp line of demarcation from the relatively preserved tissue.

between these two occurrences. But in 1 case the injury occurred six years before death and cannot be implicated as an etiologic factor, while in the other a mild trauma (2 plus) occurred at the onset of symptoms of brain tumor fifteen days before death, in a case bilateral occipital lobe metastases from a Wilms

Death in this case was not sudden. Among the 7 patients with linear extravasations of blood in the brain stem there was no history of trauma.

7 Hemorrhage into Brain Tumor in Its Relation to the Histologic Type of Tumor—Of 9 cases of hemorrhage, 4 occurred in malignant primary neuroectodermal tumors, 3 in metastatic carcinomas and 2 were in benign tumors (glioma, hemangioma) (table 2).

8 Trauma in Instances of Brain Tumor in Its Relation to Blood in the Cerebrospinal Fluid—Lumbar punctures were performed on 14 patients with brain tumor who gave a history of head trauma. In 5 of these cases the trauma occurred during the clinical course of the brain tumor, and in only 2 of these 5 cases was there loss of consciousness due to the head trauma. Xanthochromic cerebrospinal fluid was found in only 1 instance, in which the trauma had been mild (without loss of consciousness), in a patient whose decline was gradual from a metastatic tumor.

9 Type of Brain Tumor in Its Relation to the Presence of Blood in the Cerebrospinal Fluid—In 21 of the 94 patients some evidence of bleeding was found in the cerebrospinal fluid. This occurred in 6 out of 24 patients with spongioblastomas, 3 out of 6 with transitional gliomas, 6 out of 32 with metastatic tumors, 2 out of 4 with ventricular tumors, 2 out of 3 with pituitary tumors, 1 out of 2 with central neurinomas and 1 out of 6 with meningiomas.

10 Hemorrhage into Brain Tumor in Relation to Blood in the Cerebrospinal Fluid—Out of 9 patients who had hemorrhage into tumors, 7 had received lumbar punctures. In only 1 case was the cerebrospinal fluid xanthochromic. This was in a case of metastatic carcinoma (primary in the thyroid) in the right occipital region, and 1 presenting no history of trauma, and in which decline terminating in death was gradual.

CONCLUSIONS

1 Sudden death in the course of brain tumor is rarely associated with hemorrhage into the tumor or trauma to the head.

2 Our material indicates that trauma to the head plays no part in the production of hemorrhage into a tumor.

960 Park Avenue—477 First Avenue

ABSTRACT OF DISCUSSION

DR. PAUL C. BUCY, Chicago. Drs. Globus and Saperstein have given a beautiful demonstration of some of those vascular alterations which are common with these malignant gliomas of the brain, and my experience agrees entirely with theirs. Although one might anticipate that hemorrhage would be a common occurrence in these cases, or from the clinical manifestations might make a diagnosis of intracerebral hemorrhage, this is not the case when the brain is examined at autopsy. I should like to ask the authors whether or not they feel as I do, that in many of these instances the sudden turn of events, whether it is sudden death, a sudden and severe aggravation of symptoms or possibly the sudden appearance of symptoms when none were present before, is actually due to thrombosis of vessels, either in the tumor or, in many instances, in the arteries of the brain which pass either through the tumor or in close relationship to it? Many times, as Dr. Globus and his associate have pointed out repeatedly in the past, patients who apparently are perfectly well suddenly develop evidence of intracranial disease, often with a hemiplegia or other neurologic disturbance which leads at the time to the diagnosis of a cerebral vascular accident or throm-

bosis as the condition responsible for the symptoms, yet subsequent examination discloses that a brain tumor, often a malignant glioma, was the fundamental disease.

DR. JOSEPH H. GLOBUS, New York. I agree with Dr. Bucy, at least in his interpretation of what takes place in the brain when a new set of symptoms appear in the course of a brain tumor. I agree with him that it is usually due to an occlusion of a blood vessel, either by external pressure from an adjacent tumor tissue or by some inherent changes within the vessel itself, and therefore a new area of dysfunction is set up as the result of softening of the brain in the area of the occluded blood vessel. This may sometimes occur even in benign tumors. Meningiomas may often pass through an area and in a similar fashion occlude a blood vessel and give rise to a new set of symptoms. I do, however, maintain that hemorrhage is not a common feature resulting in this change of clinical picture. It is more likely, as Dr. Bucy has said, due to thrombosis.

SOME REFINEMENTS IN RECONSTRUCTIVE SURGERY OF THE FACE

FERRIS SMITH, M.D.

GRAND RAPIDS, MICH.

Organized medicine and surgery is confronted now with its particular responsibilities in another great war. It will make the most constructive contribution to this vast destructive cataclysm.

The government has a solemn responsibility to the soldier. It is morally obligated to return him to civil life, if he returns at all, in a condition as good as or better than when he was called from his peacetime environment. He must be returned, if possible, in a condition which will permit him to take his place in society without prejudice and to compete without handicap in the most strenuous economic struggle of all history.

The National Research Council at the request of the surgeon generals of the Army and Navy, has compiled directives for the guidance of the military and naval surgeon which contain the best in the literature and practice.

This in some respects is an advance over previous preparation. It is particularly true of the preparation for reconstructive surgery. Those responsible for training and medical intelligence in the several armies engaged in the last war failed to collect, review and correlate the isolated but rather complete literature.

This resulted in a reconception of methods, trial and error and many bad repairs before standards were established. Much good resulted from this necessity—this experience—but none of the errors should be repeated.

The plastic surgical experience of the last war was a great contribution and a stimulus to better reconstruction. It crystallized and standardized numerous procedures. It contributed several important new methods which revolutionized plastic procedure and increased greatly the possibility and variety of useful repair. Among these was the "tubing" of the pedicle of a flap to reduce the possibilities of infection and to permit the safe transference of tissue from a distance.

The influence of the tubed pedicle on the development of reconstructive surgery during the past twenty

Owing to lack of space this article has been abbreviated for publication in THE JOURNAL by the omission of figure 11. The complete article appears in the author's reprints.

years has been profound. This, and the availability of rotated flaps of forehead skin for repair of the nose eyelid or cheek and the use of free skin grafts has largely dominated the conception and practice of facial reconstruction.

This has been true particularly since the popularization of "thick split skin grafts" by Blain and the more recent contribution by Padgett of a mechanical means of obtaining them.

The results are more functional than cosmetic, except in certain rhinoplasties. These are "procedures of necessity" rather than the "procedures of choice," which their universal use today would seem to indicate.

This general trend of thought and procedure is unilateral thought in respect to the dual responsibility of the surgeon—to restore to normal, or as near to normal as possible, both function and appearance.

The thinking must become bilateral if the surgeon is to discharge his obligation to the civilian and the soldier. The objective must include restoration of both function and appearance. The latter precludes any plan of repair which

adds a single unnecessary scar or foreign tissue to any visible portion of the body. The pendulum should swing for the present to the other side of the surgeon's responsibility. The art and finesse of reconstructive surgery should receive more consideration. His major thought in planning and execution should be directed toward a better, more acceptable final appearance. He should

realize that the end results of pedicled flaps, rotated forehead flaps and free skin grafts are such that they should never be considered procedures of choice for facial repair even though they must be employed frequently as procedures of immediate necessity. When this is the only procedure available, the planning should contemplate the ultimate replacement of the transplanted skin, with normal skin from the vicinity whenever possible. I have never seen a transplanted skin flap that matched and blended with its surroundings. It becomes the most noticeable and prominent feature of the face even under the best of circumstances. It is frequently pigmented or has a glazed, grayish white cast and is necessarily framed in a scar of varying dimension. Utilization of the skin of the forehead results in a disability which can never be corrected.

Two important and essential principles of repair were ignored or given scant attention during the last war and have received little more consideration since, except in isolated quarters. I refer to the Z plastic procedure and multiple excision. The former was first described by Denonvilliers¹ in 1856 and the latter by

Morestin² in 1915. Z plastic has been discussed in the literature occasionally since as a method of correcting scar contractures. It has had wide employment in this connection, but numerous other possibilities of its usefulness, both alone and in combination with other principles, appear to be unappreciated.

Davis and Kitlowski,³ in an article published in 1939 dealing with the usefulness of Z plastics for the correction of scar contractures, state "We find that there are many who do not understand the procedure at all, or realize its usefulness."

"Multiple excision" is the term utilized by Morestin to describe a method of correcting a surface deformity by repeated partial removal and the replacement of the excised portion with normal tissue from the border of the defect. The extent of each removal and replacement is determined by the amount of skin and subcutaneous tissue which can be shifted into the area at each procedure. Repeated procedures of this sort at proper intervals are possible because the skin subsequently returns to its normal tension and elasticity.

Fig 1—Unhealed traumatic loss of the nasal columella tip and mesial portions of both alae (left). Tubed pedicle formed from a rectangular flap removed from the neck for transference of hairless retroaural skin to the nasal defect. Relaxation sutures and buttons (middle). Final results (right). Note the extent of the repair which is practically identical with the healed lesion in figure 2. (Courtesy of Dr Chure Straith. *Am J Surg* 43: 226 [Feb.] 1939.)

It is a most important and useful procedure alone or employed in conjunction with other methods of repair.

The employment of the principles of Z plastic, multiple excision and interpolated flaps from the vicinity of the defect should have first consideration in the planning of a correction whenever the surgeon can choose his procedure. The methods in common practice today, as evidenced in the current literature and observations in various centers, should be procedures of necessity only. They should be employed with the intention of removing ultimately the transplanted skin covering whenever possible.

I am able to contrast typical examples of the current conception of repair, as recorded in recent journals and observed among the patients of my contemporaries, with the results obtained by utilization of Z plastics, multiple excisions and interpolated flaps from the neighborhood and combinations of these methods through the permission of authors, publishers and colleagues to use their material. The cases here cited are examples of

the excellent technical accomplishments of master surgeons. They represent the types of repair that fill the files of every good plastic surgeon.

REPAIR OF THE NOSE

The loss pictured in figure 1 includes the nasal tip, small mesial portions of each ala and the columella. The tissue requirement for reconstruction is an epithelial lining and hairless covering skin which will blend with the nose in color and texture. The skin should be of such consistency or carry with it sufficient subcutaneous fat to restore contour.

This tissue may be obtained from a distance and transferred on a tubed pedicle either directly or on a

ently very satisfactory. It is an example of a universal method—a type of planning.

There is an unnecessary long suture line and relaxation stitch scars in visible portions of the neck and a graft behind the ear. Two cosmetic disabilities have been created in correcting a third.

Fig. 2—Healed traumatic loss of the nasal columella tip and mesial portions of both alae (A). Incised, grafted and delayed flap to furnish lining and surface skin for the repair (B). Final appearance after removal of grafted skin by multiple excision (C and D). Compare figure 1 (Manual of Standard Practice of Plastic and Maxillofacial Surgery, Philadelphia: W. B. Saunders Company, 1942).

“carrier” or it may be obtained locally (nose) and supplemented by a free graft of skin which will match as closely as the transferred flap.

The surgeon in this instance chose the hairless skin over the mastoid area. He constructed a tubed pedicle to carry this skin to the nose and maintain its nourishment until it acquired an adequate blood supply from the borders of the defect. The denuded area behind the ear was grafted with skin which will not blend with its surroundings. The tube was scrapped after serving its purpose. The technical accomplishment of these procedures is excellent and the result obtained is appar-

Fig. 3—Atrophy of the skin. Ectropion from infraorbital scar contraction (radiated nevus) (left). Final appearance after repair with an inframammary tubed pedicle transferred on the hand as a carrier. Note the excellent patch. Color contrasts are not visible (right). Compare figures 8 and 10 (Wilmoth C. L., The Tubed Pedicle Graft in Facial Reconstruction, Am. J. Surg. 53: 300 [Aug.] 1941).

The case pictured in figure 2 presents a similar loss with the same requirement. The planning in this instance was based on a desire to avoid any cosmetic disabilities distant from the local loss and to obtain, at the same time, a pleasing reconstruction. This was accomplished by a combination of a grafted rotated flap from the border of the defect, a free graft on the denuded nasal dorsum and subsequent removal of this graft by multiple excision. No added scars were created about the face and neck.

The tip of the nose may be restored in a similar manner. Sufficient skin from the dorsum is rolled downward to provide contour and substance and the defect of the dorsum corrected with a free skin graft taken from behind the ear. The skin defect on the ear is approximated and leaves an invisible scar.

The graft on the nasal dorsum may blend with its surroundings satisfactorily, and, if it does not, it is removed by multiple excision.

The restoration of the columella alone should not be accomplished by rotating flaps from the lip or surrounding cheeks. Two methods, other than the one demon-

Fig. 4—Flap transferred on a tubed pedicle from the upper arm for reconstruction of the mouth and cheek. Fourth degree burn in infancy. Appearance eighteen years after repair. The patch is the most arresting feature of the face.

strated in figure 2, which do not result in added visible deformities are available

One of these methods provides the required tissue by grafting a flap on the posterior surface of the upper lip and transferring it to the nasal tip as a tube, and the other by constructing a pencil tube along the upper surface of the clavicle and transplanting a portion of this. The scar running across the base of the neck renders this method unsuitable for a female casualty.

The ala may be reconstructed also without added scars about the face and neck. This may be accomplished by utilizing a delayed, reflected, hinged flap from the lateral surface of the nose above the loss to provide a lining and the rolled margin of the nostril. The total resulting surface defect is covered with a full thickness graft from behind the ear. This transplant does not match the surrounding nasal skin perfectly but rather approximately. It is as good as skin from the fore-

Fig 5—Second and third degree burn scar of the face and neck. scar contracture. See figure 6

head. Its use avoids added visible scar and confines the cosmetic disability, such as exists to the locality of the loss.

A method described by Kazanjian⁴ produces in many instances an even better cosmetic result. He outlines the ala by an incision through the skin at a proper level above the margin of the defect, separates the lining from the nasal process, divides it high in the nose and draws the alar margin down to the proper level. The resulting defect in the surface skin is covered with a full thickness graft from the back of the ear.

REPAIR OF THE FACE

It is particularly desirable that lesions of the cheeks be repaired with normal skin from the borders whenever possible. The surgeon should adopt, invariably, a plan to accomplish this whenever he is permitted to choose the procedure. No transplanted skin, either full thickness or a split portion, blends with its sur-

roundings sufficiently to prevent the repaired area from becoming a definite cosmetic disability—the most noticeable feature of the face. This is true not only of the ideal examples of such results but distressingly so in

Fig 6—Final appearance of patient shown in figure 5 after the employment of double tubed pedicle abdominal flaps transferred on the hand and arm as a carrier (right). An excellent repair employing the procedure of necessity. (Figures 5 and 6 courtesy of Dr. Gustave Aufrecht.)

Fig 7—A woman aged 27 after replacement of a hemangioma of the cheek, lower eyelid and upper lip. The lesion on the cheek and upper lip was replaced at the age of 18 with a full thickness skin graft. A thick Thiersch graft was employed for the lid. The color contrasts do not appear adequately. Compare figures 9 and 11. (Padgett E. C. THE JOURNAL Jan 2 1932 p 18)

many ordinary instances. It is possible for the female patient to mask such defects with various types of "makeup," but this is hardly desirable for a man in any capacity.

⁴ Kazanjian V. H. Plastic Repair of Deformities About the Lower Part of the Nose. Tr. Am. Acad. Ophth. 1937

I am fortunate in having the permission of my colleagues, who are master surgeons, to use their contemporary material to illustrate this contention.

The case illustrated in figure 3 is an atrophic deformity with ectropion of a lid resulting from the pull of contracted scar. The surgeon had a choice of procedure. He elected to excise the deformity and repair the defect with a tubed inframammary flap transferred on the hand as a carrier. The technical accomplishment is excellent. The cosmetic result is a patch representing

patient to blush in this patch. It approximates but does not blend with the surrounding skin. It is the most noticeable feature of the face. It has served its purpose long since and should be removed by multiple excision to bring normal skin into this area.

Figures 5 and 6 feature a case in which the introduction of new skin from a distance was a "procedure of necessity." The surgeon had no opportunity to utilize bordering skin in this repair. He has planned and accomplished skilfully one of the best cosmetic results

Fig. 8—Pigmented hair nevus (left). The lesion in the temporal region is replaced by a full thickness skin graft. The lesion on the cheek was partially removed by multiple excision and finally replaced with a split skin graft. Color contrasts do not appear. The graft remains the most arresting feature of the face (middle and right). Compare figures 9 and 10. (Courtesy of Dr. Warren Davis.)

Fig. 9—A pigmented vascular nevus presenting patches of skin atrophy and an infraorbital sarcoma as the result of roentgen irradiation and treatment with radium (left). Appearance after excision of the sarcoma, three excisions of the pigmented lesion and a Z-plastic to introduce normal skin infraorbitally without producing an ectropion (middle). Appearance three months after completion of repair (right). Compare figures 3, 7 and 8.

this cheek area. It will always remain the most noticeable feature of the face, despite the fact that it is a perfect surgical repair. (Compare figures 8 and 10.)

Figure 4 pictures an old repair (1924) of a microstoma resulting from contraction of the scar from a fourth degree burn. The skin flap was transferred on a tubed pedicle from the arm. It is one of the best in my personal experience. Its individual color is excellent. The vasomotor control is sufficient to permit the

from this procedure that I have seen. The contrast of these perfect flaps with the surrounding normal skin serves to emphasize my purpose in this discussion.

Figure 7 depicts partially the result of a free full thickness graft (see figure 9 also). It is impossible to show the color contrast that evidently exists.

The operator, Dr. Padgett, states that this graft has "some brown pigmentation" but that the patient "on the average looked pretty good." I agree that a skin

graft does not compare with the surrounding tissue. Sometimes there is some pigmentation but ordinarily ours are a little whiter in color than the normal skin." This patch, excellent as it is, is the most noticeable feature of the face.

The large pigmented hairy nevus pictured in figure 8 was removed and the area repaired by a combination of methods. The portion occupying the left temporal region was replaced by a full thickness graft from the abdomen, which the operator, Dr. Warren Davis, states "retains a lighter shade than the remainder of the normal skin." Several excisions within the nevus on the cheek and replacement of the remainder with a split skin graft (0017 mesh) from the back completed the repair.

The use of grafted skin on the temporal region was a "procedure of necessity" while the employment of a graft on the cheek was not. A continuation of the "multiple excisions" combined with a Z plastic to change the line of traction on the lower lid would suffice to replace the nevus with normal bordering skin.

by a Z plastic to introduce normal skin from the neck into the cheek and subsequent multiple excisions.

The patient seen in figure 11 presents a loss of the major portion of the left half of the upper lip, decided atrophy and pigmentation of the soft tissues of the infraorbital area of the face and lateral half of the nose and ectropion of the left lower lid. This resulted from early treatment of a nevus with radium and roentgen rays.

The surgeon had a "choice of procedure" in repairing each of the several defects. The lip has been restored by utilizing rotated flaps of the skin and subcutaneous tissue from the border of the defect without any damage to the muscles of expression. This procedure is sufficient to construct good lips with normal skin covering in all cases in which the bordering tissue is not destroyed or is so badly damaged by scar as to be useless (compare figures 12 and 13). The atrophied, pigmented skin of the face was replaced by normal skin as the result of multiple excisions and Z plastics. The eyelid was repaired by releasing the margin of the lid creat-

Fig 10—Scar from a third degree burn, destruction of the nasal skin covering and the left ala, hypertrophied scar and keloid (left). The nose has been covered with whole thickness skin from the mesial surfaces of the ears. A Z plastic has placed normal skin in position for multiple excisions of the hypertrophied scar on the cheek (middle). Appearance as the reconstruction nears completion. The Z plastic for removal of the scar on the lip is incomplete (right).

This result affords the opportunity of comparing the cosmetic value of full thickness and split portions of skin on the same patient. The procedure, despite its skilful execution, replaces a decided cosmetic blemish with another of less degree which remains a definite disability (compare figures 9 and 11).

The patient featured in figure 9 presents atrophic patches of the skin of the cheek and an infraorbital sarcoma as the result of repeated roentgen irradiation of a pigmented vascular nevus. The surgeon had a "choice of procedure" in this instance. A procedure consisting of multiple excision and the use of Z plastics to determine lines of traction was elected. The cosmetic disability consists of a fine line scar in front of the ear and line scars in the nasolabial groove and infraorbital region. The face is covered with normal skin.

The patient pictured in figure 10 presents a third degree burn scar covering the entire nose and areas of hypertrophied scar and keloid in the cheek. The nose has been recovered with full thickness skin taken from the back of both ears. The gross scar and keloid on the cheek and about the mouth has been removed

ing adhesions between the two lids and grafting the resulting defect with skin removed from the upper lid (compare figures 3, 7 and 9).

The patient shown in figures 12 and 13 presents a loss of the mental segment of the mandible, the floor of the mouth, a portion of the left upper lip, the left half of the lower lip and a small portion of the adjacent cheek as the result of a gunshot.

The plan of repair admits "choice of procedure." The surgeon chose to bring in tissue from a distance on a tubed pedicle. He has not only introduced skin into the face which will not match its surroundings but has created a large scar on the neck and chest. The defect could have been repaired with normal skin from its margins and the scars confined to its borders. This is an excellent example of the generally accepted type of planning and procedure (compare figure 11).

SUMMARY

1 The evolution of and the universal modern practice in facial repair has been profoundly influenced by the popularization of tubed pedicle flaps, free grafts and rotated flaps from the forehead.

2 Reconstructions utilizing these methods are procedures of necessity and not procedures of choice

3 The cosmetic result of such repairs merits more consideration

4 A better understanding of the varied uses of Z plastics, the employment of the principle of multiple

Fig 12—Gunshot wound. Loss of the mental segment of the mandible, the floor of the mouth, a portion of the left upper lip, the left half of the lower lip and a small portion of the adjacent cheek. Prosthetic piece in the mandible, a skin pedicle tubed on the neck and chest, large scar on the neck and chest.

Fig 13—The floor of the mouth of the patient shown in figure 12 was repaired with the skin pedicle. Stump of the tubed pedicle and a large scar on the neck and chest (right). Compare figure 11. (Figures 12 and 13 courtesy of Drs John Kemper and Reed Dingman.)

excision and the use of flaps of normal tissue from the vicinity of the deformity will improve greatly the end results

5 The plastic surgeon in this war has a solemn obligation to the soldier as well as to the casualty victim in civil life which can be discharged only by careful consideration of the art and finesse of the practice

ACUTE ENCEPHALITIS

MILD EPIDEMIC OBSERVED AT STATION HOSPITAL,
FORT SAM HOUSTON, TEXAS

JOHN C WOODLAND, MD

Colonel M C U S Army

AND

FMMETT M SMITH, MD

Major M C U S Army

FORT SAM HOUSTON, TEXAS

Thirteen cases of acute, epidemic encephalitis which have occurred in soldiers at the Station Hospital, Fort Sam Houston, Texas, seem to substantiate the suspicion that this disease may exist clinically but defy positive laboratory recognition. Case 4 (tables 1 and 2) was proved by laboratory investigation to be due to the western equine strain of virus but clinically and symptomatically the patient's disease differed in no way from the others observed in this epidemic.

At times we have been confronted, especially during the summer months, with a problem of accurately diagnosing obscure acute febrile conditions, and the summer of 1941 proved to be no exception. In late July and early August 13 soldiers were admitted to the contagious disease section of our hospital suffering from what proved clinically to be a definite and similar disease entity. The outstanding symptoms and clinical conditions noted in these cases were initial chill, fever, severe headache, rigidity of the neck, backache, vertigo, mental confusion, disorientation and some nausea and vomiting. In 5 of these cases there was present a typical saddle back fever curve which is often observed in virus diseases. Bradycardia was noted in 8 of the 13 cases.

White blood cell counts ranged from normal to a moderate leukocytosis, except in 1 instance, in which a definite leukopenia was found. Determination of the sedimentation rate in 11 of the 13 cases showed 7 definitely increased at one hour. Insomnia was rather conspicuous in 2 cases. Backache and joint pains were so severe at times that dengue fever was considered as a possible diagnosis. Neurologic findings varied from time to time. Nine patients had increased deep reflexes.

One patient required repeated catheterization. Ten of the 13 manifested some nervous disturbance. The Kernig sign was positive in 3 cases only. One patient complained of diplopia and 1 of photophobia. Ankle clonus was positive in 1, this patient also manifested coarse tremors of the fingers, hands and tongue. Sixty-three spinal fluid examinations made in these cases revealed rather constant and characteristic findings, namely increased cell count, in the neighborhood of 200 to 300 cells, a differential count showing predominantly lymphocytic type cells, total proteins ranging from 40 mg to 124 mg per hundred cubic centimeters, positive globulin found in 7. The spinal fluid pressure was slightly increased. All smears and cultures were negative for bacteria.

Released for publication by the War Department Manuscript Board which assumes no responsibility other than censorship for the contents of this article.

Owing to lack of space this article has been abbreviated in THE JOURNAL by omission of a review of available information. The complete article appears in the authors' reprints.

Of this group of 13 patients, 12 of the soldiers had been on a maneuver in Uvalde County, Texas, from ten to fourteen days prior to the onset of symptoms. One soldier, a member of the Air Corps, had spent a night at Brownsville, Cameron County, Texas, about ten days prior to admission. He stated that while sleeping in his plane to protect a cargo of supplies he suffered many mosquito bites.

In both Uvalde and Cameron counties many cases of equine encephalomyelitis in horses had been observed and reported, early in July, by veterinarians of the state and the army. It will be noted that the epidemic in animals occurred about one month prior to the onset of symptoms in the soldiers included in this report.

The disease was self limited in its course, and all the men who had been ill were returned to a duty status following an uneventful recovery in about eight weeks. No fatalities occurred.

In all cases blood was drawn at the time that the diagnosis was made, at the end of three weeks and again at the end of eight weeks. Serum was forwarded to the Army Medical School Laboratory, Washington, D. C., for confirmation of the diagnosis and identification of virus, but, as stated before, out of this group

of 13 cases 1 case only was proved by laboratory tests to be due to a known virus, namely the western equine strain.

Up to the present time encephalitis has not received much consideration as a disease to be reckoned with among our troops. As a matter of fact very few cases thus far have been recognized and reported by the Army. But with the advent of a constantly expanding military force and with large concentration of troops in urban areas, it is only reasonable to suppose that the summer months will bring an increasing number of cases of this disease.

The veterinary profession has long since recognized the seriousness of encephalomyelitis in horses and mules. Members of the Army Veterinary Corps, such as Kelser, Reynolds and others, have done outstanding pioneer work in the investigation of this disease. They have undoubtedly made great strides in the protection of animals with a bivalent vaccine. The Army Medical Corps should be constantly on the alert in order to recognize and to handle intelligently epidemics of encephalitis, since our troops are now, or soon will be, in areas of the world where this disease is known to exist, such as Australia, Japan, Russia and various sections of the United States.

SUMMARY AND CONCLUSIONS

1 It is apparent from published reports that epidemics of acute infectious encephalitis are increasing in frequency and severity

2 Epizootic epidemics should be considered as warning signals of the possible transmission of the disease to military personnel in infected areas. Close cooperation between medical and veterinary professions is therefore essential

3 The 13 cases of acute infectious encephalitis herein reported presented identical features. However, 1 case only was positively identified as being caused by a known strain of neurotrophic virus, namely the western equine

4 It is our opinion that further investigation will reveal other strains of neurotrophic viruses or will disclose alterations in the biologic activities of those already identified

5 Acute encephalitis is self limited in its course. The cases under our observation manifested acute symptoms for a period of about one week. Thus the disease, in mild epidemics, may be easily overlooked

6 Treatment is mainly symptomatic. Lumbar punctures and intravenous saline solution gave dramatic relief from the severe headaches. Sedatives were used when necessary. The sulfonamide drugs were not found to be of any value

7 The prevention and control of this disease deserves the thoughtful consideration of all members of the Medical Corps of the Army. The approach to the problem should be considered under two heads: (a) the control of the reservoirs and vectors of the disease by immunization and isolation of animals and the eradication of the known vectors and (b) the use of a purified vaccine for the immunization of military personnel if the disease should become epidemic in areas of large troop concentrations

8 For a differential diagnosis in this epidemic we were confronted with the signs of diffuse cerebral involvement, i. e., nausea, vomiting, stiffness of the neck and varied neurologic manifestations. At the time of admission to the hospital a severe influenza or meningismus was thought of. The laboratory examination made on the spinal fluid aided in differentiating these diseases. Spinal fluid was constantly negative for organisms, the sugar contents were normal. These factors, together with the rapid clearing of the symptoms, removed the specific meningitides from the picture

Paralysis of muscle groups was not seen, therefore, poliomyelitis was not seriously thought of. In none was there a history that would point to a diagnosis of postinfectious encephalitis. The fact was soon evident that we were dealing with a disease entity occurring in the summer months in a group of soldiers who had been on a maneuver in Uvalde County, Texas, where equine encephalomyelitis had been diagnosed and reported

The disease entity presented all the clinical manifestations of a neurotrophic virus disease. Laboratory investigation, however, failed to reveal the specific virus responsible for the epidemic, except in 1 case (case 4), the course in this case differed in no respect from the others

The wide use of sulfonamide dusting powders for the treatment of war injuries caused the Food and Drug Administration to make an intensive study of the bacteriologic flora of the preparations on the market. Approximately 50 per cent of the powders examined by us contained viable bacteria, namely staphylococci, streptococci, diphtheroids and both aerobic and anaerobic spore forming organisms¹. It was of interest that a large number of powders examined, although not sterilized following manufacture, were found to be sterile. Those sulfonamide powders examined which had been processed in the final package to destroy organisms that may have been present were invariably found to be sterile. Following these studies the Food and Drug Administration issued a letter requesting that manufacturers of sulfonamide drugs promptly take the steps necessary to sterilize these drugs and to package them so as to prevent contamination. Recent examinations made of sulfonamide powders have indicated that the sterilization processes developed by the manufacturers have been effective in producing sterile powders

Although in the bacteriologic analysis of these drugs pathogenic anaerobes were not isolated, this cannot preclude the possibility of such contamination since anaerobic sporeforming organisms were found with considerable frequency. The presence of such organisms as *Clostridium tetani*, *Clostridium perfringens*, *Clostridium oedematiens*, *Clostridium fallax*, *Clostridium septicum* or even *Clostridium sporogenes* in sulfonamide dusting powders to be used in deep wounds constitutes an added and unnecessary hazard which can easily be avoided by proper sterilization. Since the sulfonamides act largely through bacteriostatic effect rather than through bactericidal action, it could not be expected that they would be active against spores or that such drugs would be self sterilizing

Numerous observations during the war of 1914-1918 showed the presence of *C. tetani* in the wounds of men who exhibited no symptom of the disease. In the examination of the wounds of 100 soldiers not suffering from tetanus, Tulloch² found this organism nineteen times. It was also demonstrated that tetanus might not develop for weeks or months after the wound had healed and then might suddenly appear following an operation, perhaps on another part of the body. Although prophylactic use of tetanus antitoxin prevented the immediate development of the disease, this procedure had no destructive effect on the spores themselves, which could and did lie dormant at the site of

after the primary injury Bonney, Box and MacLennan⁵ reported the recovery of Cl tetani from abdominal scar tissue ten years after an attack of postoperative tetanus

We have in the present work, through the use of sulfonamide powders, a similar situation. If sulfonamide powders are contaminated with tetanus spores and are dusted into deep wounds, the bacteriostatic action of these drugs may readily prevent development of vegetative forms. With the subsequent absorption of the drug and final healing of the wound, tetanus spores may be left at the site of the wound for possible future development when the proper conditions for vegetation of the spore forms are made available.

Tetanus toxoid is being used by both the Army and the Navy for protection of their personnel, and undoubtedly a large percentage of those treated will have adequate protection. However, very few of the civilian population will have advantage of this prophylactic measure.

In the present investigation a study has been made of the effect of sulfanilamide dusting powder on a suspension of washed tetanus spores implanted into guinea pigs, which are known to be readily susceptible to experimentally induced tetanus. The strain of Cl tetani used was a laboratory stock culture and produced a moderate amount of toxin. The tetanus spore suspensions were prepared in chopped meat culture under Vaspar seal, washed free from toxin with distilled water, and then heated at 82 C for twelve minutes to destroy vegetative forms. For implantation the hair was removed with electric clippers from an area about 2 inches in diameter on the right flank of the animal. Under local anesthesia an incision about 2 cm long was made through the skin, parallel to the spine, anterior to the hip joint. By means of blunt dissection with a hemostat a subcutaneous pocket was prepared in the plane of cleavage between the skin and the deeper structures and extended about 3 cm along

the flank of the animal. The pocket was held open with forceps and the sulfanilamide powder insufflated into the cavity until it was approximately half full. The desired number of tetanus spores suspended in 0.1 or 0.05 cc of distilled water were then dropped onto the powder from a hypodermic syringe. After addition of the tetanus spores the pocket was filled to overflowing with sulfanilamide, and one or two skin clips were then used to close the opening. The clips were removed when the wound had healed (usually forty-eight hours). Ninety guinea pigs were treated in this manner.

In the preliminary implantations 20 animals were used. These were divided into five groups of 4 each and each group inoculated with 100,000, 10,000, 1,000, 100 and 10 spores, respectively. After a period of approximately sixty-five to seventy days those animals which failed to develop tetanus were traumatized by crushing of the tissue at the point of implantation or were injected with 0.1 cc of a twenty-four hour broth culture of *Staphylococcus aureus* in the pocket area and, finally, all the animals were injected with 2 cc. of 10 per cent kaolin suspension containing 10 mg of calcium chloride. The results are given in table 1.

It will be noted that 1 guinea pig in the group treated with sulfanilamide and 100,000 spores and 3 in the group receiving sulfanilamide and 10,000 spores contracted tetanus. Tetanus did not develop in the 1,000, 100 or 10 spore groups. In spite of severe injury produced in surviving animals sixty-five to seventy days after implantation, tetanus failed to develop. The latter results are in conformity with those of Francis,⁶ who showed that although toxin free spores could be rendered pathogenic for guinea pigs by the injection of a tissue debilitant, such as quinine, it was found that,

three months after implantation, even though at autopsy all the animals showed areas of necrosis at the site of the injection of kaolin and calcium chloride.

Following the preliminary series, experiments were conducted with a further group of 70 guinea pigs. Fifty animals were used to test the efficacy of sulfanilamide, and 20 served as controls. The test group of 50 animals was divided into five groups of 10, and each group had implanted sulfanilamide and spores (100,000, 50,000, 25,000, 10,000 and 1,000 respectively). Five of the 10 animals at each spore level were, in addition, injected with 0.1 cc. of a twenty-four hour broth culture of *Staphylococcus aureus* at the time of implantation of the sulfanilamide and spores. In the control series the 20 animals were divided into five groups of 4 each and these received 100,000, 50,000, 25,000, 10,000 and 1,000 spores respectively. Two guinea pigs at each spore level were injected with staphylococci in a similar manner to those in the test series of animals. The results are given in table 2.

It will be noted that in the sulfanilamide series 2 animals in the 100,000 spore group, 1 injected with staphylococci and 1 which was not, and 4 in the 25,000 spore group developed tetanus. The latter 4 had received staphylococci as well as sulfanilamide. Tetanus was not produced in the 10,000 or 1,000 spore groups of animals, whether or not staphylococci were implanted simultaneously with the spores and sulfanilamide powder. A total of 6 animals (12 per cent) developed the disease within four to seven days after implantation and died, forty-eight to seventy-two hours after the onset of the first signs of paralysis. Ten days later all surviving guinea pigs were injected at the site of implantation with 2 cc. of 10 per cent sterile kaolin suspension containing 10 mg. per cubic centimeter of calcium chloride. It will be noted (table 2) that none of the surviving animals developed tetanus following this traumatization in the area of the original implantation of sulfanilamide and tetanus spores. When the animals were killed ten days later *Cl. tetani* could not be isolated from the original site of implantation. In all cases of tetanus, paralysis appeared first in the leg nearest to the site of implantation, and shortly thereafter complete paralysis developed and death ensued.

In contrast to the sulfanilamide series, in which 6, or 12 per cent, of the animals developed tetanus following implantation of the drug and spores whether or not staphylococci also had been inoculated, none of the control series of 20 animals developed tetanus directly following implantation of spores or spores and staphylococci. However, 4, or 20 per cent, of the control series developed tetanus following traumatization with kaolin and calcium chloride ten days after implantation, while none of the animals in the sulfanilamide series developed the disease following traumatization. It is of interest that 4 of the guinea pigs in the control series exhibited symptoms of shock and died within twenty minutes after injection of kaolin and calcium chloride, and *Cl. tetani* was isolated from the site of implantation of three of these animals. Several animals in the sulfanilamide group also exhibited the same symptoms of shock, but none died. Ten days after traumatization, all the surviving animals in the control series were killed and examined. *Cl. tetani* could not be demonstrated at the site of implantation in any of these animals.

COMMENT

Whether or not tetanus will develop when spores are introduced into a wound probably depends on the presence or absence of some tissue debilitant. Many of the so-called accessory factors, such as mechanical trauma, hemorrhage, gumine, calcium chloride, sterile earth and other agents which are conducive to the development of this disease, have been described in the literature, and it appears to be accepted that the presence of these accessory factors causes areas of necrosis which bring about a lowering of the oxidation-reduction potential, thus allowing the spores to germinate. When sulfanilamide contaminated with tetanus spores is implanted in guinea pigs, we do not have a dissimilar set of circumstances. Sulfanilamide inherently has no destructive effect on resistant spores, although it may inhibit the development of vegetative forms. The presence of a high concentration of sulfanilamide deep in the tissues may act as an "accessory factor" or foreign body, and, although this drug has little primary toxicity, in high concentrations it can undoubtedly set up areas of necrosis in some animals. Glynn⁷ has shown a slight but definite toxic effect of sulfanilamide and to a lesser extent of sulfapyridine on striped muscle of rabbits.

As soon as the action of the tissue fluids removes the sulfanilamide by solution and absorption, the tetanus spores are able to germinate and produce their toxin. That this is not invariably true, however, is shown in these studies (table 2), since only a few animals develop the disease following implantation of sulfanilamide and tetanus spores. The production of necrotic tissue by injection of kaolin and calcium chloride failed to stimulate development of tetanus in the sulfanilamide series whether the time elapsed between implantation of the drug and spores and the injection of necrotizing substance was ten days or seventy days.

On the other hand, none of the 20 animals injected with spores or spores plus staphylococci (control series) developed tetanus directly after implantation, while, following injection of the necrotizing substance ten days later, 4, or 20 per cent, succumbed to the disease. The development of tetanus in the sulfanilamide series directly after implantation and the absence of the disease under similar conditions in the control series of animals not receiving this drug lends support to the view that under certain circumstances sulfanilamide may act as an accessory factor in the development of tetanus. From our inability to produce tetanus in the sulfanilamide series following the injection of a necrotizing substance, in contrast to the results obtained in the control series, it would appear that sulfanilamide may have a destructive effect on the spore suspension implanted. This effect may result from inhibition of the development of vegetative forms and the ultimate removal of spores through phagocytosis.

Even though the results reported are on a small series of animals, the indication is that in wounds treated with sulfanilamide contaminated with *Cl. tetani* there exists a paradoxical situation in which this drug under certain conditions may act as an "accessory factor" to the development of tetanus, yet inhibit its development through a destructive or inhibitive effect on tetanus spores.

7 Glynn, L. E. The Effects of Sulfanilamide, Sulfathiazole and Sulfapyridine on the Development of Granulation Tissue and Their Toxic Action on Striped Muscle. *J. Path. & Bact.* 53: 183 (Sept.) 1941.

SUMMARY AND CONCLUSIONS

1 Sulfanilamide, contaminated with tetanus spores and implanted in guinea pigs, will not protect these animals from the development of tetanus

2 Sulfanilamide may act as a tissue debilitant and thus in the presence of Cl tetani be conducive to the development of tetanus

3 All sulfanilamide dusting powders for use in deep wounds should be sterilized before use

Since preparation of this manuscript, a case of fatal tetanus has been reported which developed following the use of unsterile sulfapyridine powder after a pelvic operation⁸

Clinical Notes, Suggestions and New Instruments

PALINDROMIC RHEUMATISM

MILTON MAZER M.D. WASHINGTON D. C.

The term palindromic rheumatism has been applied by Hench and Rosenberg¹ to an unusual disease of joints and adjacent tissues recently described by them. Characterizing the disease are multiple episodes of acute arthritis, periarthritis and occasionally para-arthritis without fever. Typically, only one, though occasionally several, small or large joints are involved in an attack, with pain, swelling, redness and disability. The attacks are sudden in onset, reach a climax rapidly and then subside, leaving no residue. Despite scores of attacks at irregularly spaced long or short intervals, irreversible changes in the joints or periarticular tissues are not found.

REPORT OF CASE

A man aged 53, who during the first world war served in France for two years, first with the Y. M. C. A. and later with the Army of the United States, was employed as a university instructor from 1919 to 1927 and as secretary of a national college fraternity from 1927 to 1934. When first seen at this hospital in 1941 he had been employed only sporadically since 1934. His past medical history included measles, mumps, pertussis, scarlatina (without sequelae) and recurrent malaria in childhood. At 7 years of age he had an acute illness, colloquially called "brain fever," with unconsciousness for four or five days. There were no evident sequelae. At 37 a tonsillectomy was performed.

Since 1912 he has had recurrent attacks of pain, swelling, local increase in temperature and bluish red discoloration of various joints. The fingers, elbows, shoulders, knees, ankles, heels and left great toe have been involved frequently, the wrists and cervical portion of the spine less often. On six occasions one or the other temporomandibular joint has been affected. Although the disease has not been limited to any particular joint, the knees and ankles were most frequently affected at the onset of the condition, while the fingers have been involved in 75 per cent of the attacks occurring in the past two years. As a rule, one joint is involved in a single attack, occasionally two or more. Occasionally attacks overlap, one joint becoming involved during subsidence of the process in another.

The typical attack begins at approximately 3 p. m., reaching a maximum intensity in two hours, persisting in such degree for about five hours and slowly abating over a period of two to three days. The pain is described as a "severe throbbing ache" and in the past it was "excruciating." It is becoming progressively milder. At the onset of the condition the fre-

quency of attacks was about every five days, a year ago it was seven to ten days, and in the past six months it has been ten to twelve days. In 1929 a complete remission lasted four months. It is thus seen that the patient has certainly had well over a thousand attacks in the thirty years of his illness.

Aside from the diffuse soft tissue reaction about the joints there has been no localized para arthritis. Intercutaneous or subcutaneous nodules have never been noted. Occasionally accompanying the joint involvement he has experienced pain over the anterolateral aspect of the upper part of the arm at the level of the biceps insertion. The left arm is the more frequently involved. The pain is increased by movement of the arm and persists for the duration of the joint involvement. There are no objective signs accompanying the pain in the upper part of the arm. Fever has never accompanied an attack. His appetite remains unchanged, and he has never lost weight ascribable to the condition. Though partially disabled he has never been forced to bed by an attack.

The attacks have no temporal relationship to infections of the upper respiratory tract. Enucleation of the tonsils in 1923 was without effect. His teeth have always been in good condition and well cared for. He believes that excessive walking may precipitate attacks involving the knees. The state of the weather or change of climate does not appear to influence the condition.

There is no personal or family history suggestive of the presence of an allergic state. No relationship of the attacks to the ingestion of any specific foods has been noted, although he believes he is better when partaking of a fairly light diet containing little beef. Cinchophen has been the most effective symptomatic remedy used. However, he has had no tophi, olecranon bursitis, renal calculi, fever or any other significant sign usually associated with gout. Nonspecific vaccine therapy and iodides were without effect. A low purine diet was likewise ineffective.

The earliest examination data of which are available, was performed by Dr. P. S. Hench² at the Mayo Clinic in August 1929. The physical examination including that of the joints showed no abnormalities. The urine contained a faint trace of albumin and an occasional pus cell, the hemoglobin content was 80 per cent, the red blood cell count 4.4 million, the white blood cell count 6700, the reaction to a flocculation test for

Fig. 1—Absence of permanent changes in the hands after large number of attacks.

syphilis negative and the uric acid content of the blood 3.4 mg. per hundred cubic centimeters. Dental roentgenograms and examination disclosed no evidence of infection. Roentgenograms of the feet were normal. Prostatic secretion showed evidence of a prostatitis.

He was first examined at this hospital on May 15, 1941. The general examination and also that of the joints (fig. 1)

1 Hench, P. S., and Rosenberg, E. F. An Oft-Recurring Disease of Joints (Arthritis, Periarthritis, Para-Arthritis) Apparently Producing No Articular Residues: Its Relationship to Angioneurotic Arteritis, Allergic Arthritis, and "Atrophic Arthritis." Presidential address of Dr. Hench before the American Rheumatism Association, New York, June 11, 1940, *Palindromic Rheumatism*.²

revealed no abnormalities. Laboratory studies were negative: the urine was normal, the blood uric acid content was 3.5 mg, the blood sugar content 79 mg and the blood nonprotein nitrogen 24 mg per hundred cubic centimeters. X-ray examination of both knees, ankles, feet, elbows, wrists and hands showed no evidence of joint abnormality (figs 2 and 3).

Fig 2—Absence of joint changes in hands

He was seen on May 27 during an acute attack. There were moderate swelling and an increase in temperature of the phalangeal joint of the right thumb and the first phalangeal and metacarpophalangeal joints of the third finger of the left hand. There was no significant discoloration of the skin.

On Feb 5 1942 he was examined between attacks, with negative findings. He reported that since October 1941, when he had secured satisfactory employment, his attacks had become less frequent and significantly milder. At this visit laboratory studies showed red blood cell count 4.8 million, hemoglobin 14.3 Gm per hundred cubic centimeters, white blood cell count 9,000, with a normal differential count, and sedimentation rate 35 mm in one hour.

On March 28, during an acute attack, there were pain, swelling, redness and local increase in temperature in the metacarpophalangeal joint of the second finger of the right hand. The attack had begun two days before and was subsiding. A few hours before the examination pain had begun in the right knee, and the joint was red and warm though not yet swollen.

On May 12 in an interval between attacks, the blood cholesterol content by Bloor's method was 263 mg per hundred cubic centimeters.

COMMENT

The most unusual feature of the syndrome described by Hench and Rosenberg³ and in the case reported is the absence of permanent changes in the joints after recurrent attacks of acute arthritis over long periods (figs 1, 2 and 3). The patient certainly had over a thousand attacks in thirty years, and yet all the joints were clinically and roentgenologically normal. Histologically, material from two joints between attacks was entirely normal.³ Biopsy of material taken from two acutely involved joints and one tendon showed an inflammatory polymorphonuclear exudate. Significant numbers of eosinophils were not seen.³

Hench and Rosenberg³ have considered the etiologic possibilities in some detail. Neither the evidence for an infective nor an allergic mechanism was conclusive, and no conclusions were drawn. In a group of 54 cases of an unusual type of arthritis described by Kahlmeter⁴ and similar in many respects

to palindromic rheumatism, the author indicated his belief in an allergic origin by his designating the condition allergic rheumatism. A syndrome similar to but differing in some respects from both palindromic rheumatism and allergic rheumatism was described by Solis-Cohen⁵ under the term angioneural arthrosis. This syndrome appeared in persons with evidence of vasomotor instability. The two conditions are similar in some respects but not in others to palindromic rheumatism, but further study will be required to determine whether they are the same or distinct conditions.

Since there is no adequate evidence for either an infectious or an allergic cause of palindromic rheumatism it may be fruitful to speculate concerning another possibility, namely psychogenic factors, as has been suggested for other types of arthritis.⁶ In the case herein reported there are two periods which suggest such a possibility. Coincident with securing satisfactory employment after a seven year period of almost complete unemployment the severity of the patient's symptoms decreased and the frequency of attacks became less. He ascribed the change to the institution of more regular habits of eating and sleeping. In 1929 he had a complete remission of symptoms for four months. He attributed this to the use of orthopedic shoes. It must be noted however, that the shoes were prescribed under conditions of heightened suggestibility at a medical shrine in another country. During the interviews no frankly neurotic symptoms were elicited, though his failure to marry is suggestive of incomplete adjustment. One of Hench and Rosenberg's³ patients 'adopted a baby quit worrying about herself and was cured.'

The nature of the disease itself is compatible with either a metabolic or a psychologic causation. The complete reversibility of the pathologic process even after hundreds of attacks certainly is not typical of infectious states. Even allergic reactions leave organic residues after repeated attacks. The presence of local inflammation certainly does not limit one to an infectious cause any more than the local and general pyrexia do in gout. Interesting in suggesting the presence of a metabolic disturbance is the observation of Hench and Rosenberg³ that blood fatty acids and total lipids are moderately elevated.

SUMMARY

A man aged 53 had frequently recurrent acute arthritis of thirty years' duration without permanent changes in the joints.

Fig 3—Absence of joint changes in knees

The syndrome conforms in all significant respects to palindromic rheumatism, 34 cases of which were described by Hench and Rosenberg,³ and is so classified.

Special Articles

HANDBOOK OF NUTRITION VII

IRON IN NUTRITION

REQUIREMENTS FOR IRON

CLARK W. HEATH, M.D.

LOSTON

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed.

In spite of evidence to the contrary, the idea is still current that when the diet is deficient in iron the red cells soon become deficient in hemoglobin (hypochromic) and smaller (microcytic) than normal. This idea is certainly not true for the healthy adult male or for healthy women after the menopause. It may sometimes be true for growing children and for women during their menstrual life or during pregnancy or for any person who has lost or is losing considerable amounts of blood from some lesion of the body. Much remains to be learned about the metabolism and functions of iron, but of this we can be quite sure: a diet deficient in iron has not been known to produce iron deficiency except in the presence of increased needs for iron such as growth, pregnancy or blood loss.

One basic fact is essential in any adequate consideration of iron deficiency: iron is an element and unlike certain organic substances of the food which are necessary to the body, such as the vitamins, it is not destroyed or used up in the body but is conserved and, if not excreted, can be utilized again and again. Another important fact concerning iron is that it is not excreted by either kidney or intestinal tract in appreciable quantities. It has been called a "one way substance," that is, it may be absorbed, or if not absorbed it will be eliminated in the stools but, in any ordinary sense it is not excreted. The iron content of the normal human urine is very small. Lintzel¹ regarded it as negligible, less than 0.02 mg. per liter. Marlow and Taylor² found values for urinary iron ranging from 0.03 to 0.8 mg. in twenty-four hours. Lanyar, Lieb and Verdino³ found less than 0.01 mg. of iron per liter of urine. The iron of the urine is not increased significantly even after destruction of the red blood cells by phenylhydrazine.⁴ It may be increased immediately after the administration of inorganic compounds parenterally.⁵ Hahn and his associates,⁶ in a study of dogs which were given radioactive iron as ferrous gluconate by vein, found an extra output of iron in the urine and feces for a few days after its injection (2 to 8 per cent

of the total amount injected). Following this the urinary iron dropped to traces, but the stools contained from 0.05 to 0.4 mg. of radioactive iron daily. The bile contained insignificant amounts of iron, which confirms the findings of others. The authors considered the evidence conclusive that the dog excretes iron only with difficulty and in small amounts. Maddock and Heath⁶ decided from microscopic study of the gastrointestinal tract and of colonic explants on the abdominal walls of dogs before and after the administration of iron that iron cannot be observed to be excreted by these organs.

Studies of the balance between the iron ingested and the iron contained in the urine and feces indicate no excess of the latter over the former (negative balance) and indeed there is a necessary positive balance in the case of children and pregnant women. This is illustrated in the summary shown in table 1. An exception is the case of the two fasters Cetti and Brethaupt. Here, however, the experimental periods were short, the methods probably faulty and the conditions of fasting are in no way comparable to ordinary nutritional circumstances. Particular note should be made of the observations of Lintzel. In his experiments even when the diet contained as little as 0.9 mg. of iron daily, the caloric intake being adequate, iron balance was reached within a few days.

To the evidence of the chemical and microscopic studies which show meager iron excretion from the body may be added the evidence from certain clinical observations. Study of patients having hypochromic anemia which is alleviated by iron medication shows that serious blood loss can usually be demonstrated in such patients. In so-called idiopathic hypochromic anemia careful clinical study of cases has shown the wide prevalence of abnormal blood loss usually from menorrhagia or bleeding hemorrhoids and often occurring in a subtle and chronic form. The evidence is so overwhelming that iron deficiency occurring in men and women is associated with abnormal blood loss that, even in the presence of very poor diets and conditions of the gastrointestinal tract which interfere with the absorption of iron, a history of blood loss in such cases is always to be expected and should be most carefully searched for. I have not yet observed such a case which I felt could reasonably be supposed to have resulted from a prolonged negative iron balance.

In contrast to the very small amounts of iron which are lost from the body by the renal and gastrointestinal routes are the significantly large amounts of iron which may sometimes be shown to be absorbed. The metabolism experiments of Fowler and Brer⁸ and of Brock and Hunter⁹ show that an astonishingly large amount of iron may be retained by the body. Retention of over 6 Gm. of iron in an experimental period has apparently been demonstrated, more than the amount of iron assumed to be present normally in the body. That the body in certain cases can retain large amounts of iron is demonstrated in hemochromatosis in which over 50 Gm. of iron may be recovered from the tissues. In this disease there may be disturbance of a control mechanism which limits the retention of iron in normal

individuals. In dogs and in man it has been demonstrated that iron is retained in larger amounts when there is need for materials for blood regeneration.¹⁰ The iron is apparently absorbed largely in the upper small intestine and perhaps in the stomach.¹¹ It is conveyed in the plasma, possibly also in the red blood cells and is found stored particularly in the liver, spleen, kidneys, skin and apparently the bone marrow. In persons in good nutrition there is presumably a store of such iron which is available should a need arise, for example the need occasioned by acute blood loss.

Although it cannot be said that adult man will become anemic if his diet contains too little iron, much can be said in favor of diets containing adequate amounts of iron for the population at large. Sherman¹² has

The need for iron varies greatly at different ages and under different conditions. In growth there is a need for iron to supply the hemoglobin in the expanding blood volume. In fact, by far the greater part of the functioning iron of the body is located in the circulating hemoglobin. The blood under ordinary conditions contains more than five times the concentration of iron of any organ of the body, and its mass is considerably larger than that of the liver.¹⁴ Growth of the blood volume can be placed beside loss of blood as an important contributing cause of iron deficiency. At puberty as well as in infancy there is an acceleration of growth and an increase in the circulating hemoglobin. At puberty in girls there is also a loss of hemoglobin (and therefore of iron) in the menstrual fluid. In pregnancy

estimated the "dietary standard" of man as about 12 mg of iron daily. I estimated the diets of over 200 healthy male college undergraduates to contain an average of 16 mg of iron a day and to vary from 6 to over 20 mg of iron a day. The Committee on Food and Nutrition of the National Research Council¹³ has recommended the daily allowances for iron given in table 2.

there is an increased need for iron to supply the growing fetus. The child at birth normally has a certain amount of stored iron which is available for use. In prematurity and twin births this may be considerably limited and these infants are later vulnerable to iron deficiency. Finally, during lactation there is loss of iron which annually probably is similar in quantity to the menstrual loss. Unless iron is provided to replace what is lost or to build new hemoglobin under these conditions, iron deficiency anemia will manifest itself. Sufficient stored iron will, of course, provide the necessary iron. But, if the stores of iron are insufficient, iron must be provided through the food or through medication, if iron deficiency anemia is to be avoided. Some-

¹⁴ In any anemic state there is a diminution of the gross amount of circulating hemoglobin and also of the circulating iron. This does not mean that iron deficiency is present in all kinds of anemia. In pernicious anemia for example there is usually an adequate amount of stored iron which is available for blood formation when liver extract (without iron) is given.

times gastrointestinal disturbances such as diarrhea, achlorhydria or intestinal disease interfering with absorption will prevent iron from entering the body even though the diet has supposedly adequate amounts of iron. When this is the case an individual may maintain a low hemoglobin level for many years. The administration of large doses of inorganic iron in such cases will practically always relieve the anemia.

Tables 3 and 4 give the estimated annual iron requirements for physiologic needs of males and females and the data from which these requirements are derived. The sources for the changes of growth, blood volume and hemoglobin values with age and sex have been described in the original publication of the tables.¹⁵ A somewhat similar analysis of the growth requirement for iron has been reported by the White House Conference on Child Health and Protection.¹⁶ The figures in that report are somewhat higher, being based on the total iron content of the body. Tables 3 and 4 show that iron requirements are greatest in infancy and early childhood and about the age of puberty, and they are larger in females than males after puberty and are increased during pregnancy. At these times and under these conditions iron deficiency is seen most commonly, if we except cases of pathologic blood loss. This supports the assumption which has been made that, if physiologic needs for iron are not supplied, iron deficiency anemia will occur.

Since the physiologic factors which favor iron deficiency are universal, as well as blood loss from wounds or lesions of disease, there can be no purely geographic distribution of iron deficiency. There are, however, environmental factors which may render iron deficiency more common in certain locations. The anemia associated with hookworm infection is an anemia of iron deficiency and is found in tropical and subtropical climates. Customs restricting the activities of women, such as those of certain sects of India, may interfere in various ways with the intake of food iron. It is probable that Victorian influences circumscribing the activities of women were in part responsible for the high incidence of "chlorosis" in the past century.¹⁷

Anemia, achlorhydria and intestinal disorders appear to be more common in parts of the Scandinavian countries, England, and Scotland and North America, although hereditary influences as well as dietary customs among Nordic peoples may play a role. It is estimated that iron deficiency is present in at least 16 per cent of

the female patients entering the general medical wards of the Boston City Hospital. In an extensive study of individuals belonging to the poorest classes of northeast Scotland, Davidson, Fullerton and Campbell¹⁸ found anemia believed to be iron deficiency in 41 per cent of infants under 2 years, 32 per cent of preschool children,

2 per cent of school children, 16 per cent of adolescent women and 45 per cent of adult women. MacKay¹⁹ reported also an extremely high incidence of iron deficiency anemia in women and infants of the hospital class in London. MacKay²⁰ also presented evidence indicating that anemia of iron deficiency was associated with a higher incidence of infections. Dietary and hygienic factors will influence the incidence of iron deficiency as well as of other deficiency states in any one locality or at any one time. Cases of iron deficiency, on the other hand, will be present everywhere and at all times as long as pathologic blood loss and other factors interfering with normal physiology of iron exist.

REQUIREMENTS FOR COPPER AND OTHER METALS

The important change in the body when there is a deficiency of iron is an inability to form hemoglobin. There are undoubtedly other widespread changes in the body, examples being the dystrophy of the nails and the atrophy of the pharyngeal mucous membrane in severe chronic iron deficiency, but these are less well understood. Iron forms an essential part of the hemoglobin molecule, which is a protein in which a large molecule, globin, is linked with a smaller iron

containing molecule, hematin. In the absence of available iron, therefore, hemoglobin cannot be formed. Nevertheless there are a number of other substances which in the presence of iron have been shown to influence hemoglobin production. Whipple and his co-workers have been able to arrange certain foodstuffs, among them liver, according to their power of regenerating hemoglobin in dogs rendered chronically anemic by repeated bleeding and maintained on a diet poor in hemoglobin-regenerating factors. Bile pigment, chlorophyll and chlorophyll derivatives are effective when added to small doses of iron in increasing blood regeneration in iron deficiency. Copper has attracted particular attention as an adjunct to iron therapy, because it has been proved quite definitely that copper is a necessary substance for hemoglobin formation, at least in small animals.²¹ Copper, however, does not form a part of the hemoglobin molecule, and although it is an essential element in human tissues its functions are little understood. Iron deficiency anemia in adult man apparently responds satisfactorily to iron therapy without supplementary copper feeding. This is not proof that copper isn't needed, but only that supplementary copper is not necessary. The issue is clouded by the fact that iron preparations used in therapy, as well as most foods contain small amounts of copper. A few cases of iron deficiency in man have been treated satisfactorily with copper-free iron. Iron given parenterally in small amounts has been recovered quantitatively in the new-formed hemoglobin.²² Hemoglobin formation in certain cases of childhood anemia has apparently been hastened by supplementing iron therapy with copper,²³ although these results have not been conclusive and the thesis that supplementary copper is necessary in the treatment of iron deficiency in childhood has not been supported by others.²⁴ Other metals, such as arsenic, zinc, nickel and manganese in very minute amounts, perhaps have a similar influence to copper.²⁵ Man derives his variegated food from widely different locations, and even much limited diets may contain significant amounts of elements which are present in the body in minute amounts. This is not true of laboratory animals on controlled diets or in the cattle and sheep industry in certain parts of the world. A case in point is the peculiar anemia of cattle and sheep which graze on land the soil of which is poor in certain minerals. This has been investigated by Filmer and Underwood²⁶ in Australia, who found that cobalt is apparently the specific element which is deficient. It is extremely unlikely that specific deficiencies of these minerals other than iron, which are required by the body in minute amounts, will develop

in man. The possible exception to this is the case of infants fed on cow's milk exclusively during the first year of life.

RECOMMENDATIONS FOR SATISFYING NUTRITIONAL REQUIREMENTS FOR IRON AND OTHER METALS

Iron is widely distributed throughout nature and is probably present in all cells both plant and animal, where it serves an essential use in cellular function.²⁷ The more processed and purified foods consumed by man (e.g. cane sugar, white flour, polished rice) contain less iron as well as other accessory food substances than the cruder products. A diet containing adequate amounts of iron and other minerals should therefore be rich in animal and vegetable cells, should be broadly chosen and should have no excess of highly processed foods. Presumably, if the iron content of the diet is satisfied the content of copper, cobalt, and manganese will be satisfied. Iron deficiency anemia itself, which can and often does arise in spite of ade-

* Estimated iron requirement for pregnancy

quate iron in the food, is easily treated by the administration of adequate doses of inorganic iron preparations, for example ferrous sulfate 0.3 Gm (or more) three or four times daily, ferric and ammonium citrate 2 Gm (or more) three times daily or reduced iron 1 Gm (or more) three times daily. Smaller doses are given in infancy and childhood. Iron may be properly given as a preventive against the later occurrence of iron deficiency during pregnancy, in infancy and early childhood and in girlhood about the time of puberty.

In table 2 have been given the recommended daily allowances for iron in the diets of children, men and women as recommended by the Committee on Food and Nutrition. These figures are very much greater than the actual physiologic needs of the body for functioning iron, but only a part, usually a very small part, of the iron of the food is absorbed. A well chosen diet adequate in calories and containing meat, eggs, colored vegetables and whole grain flour will satisfy or even exceed these requirements. Although such diets would certainly be adequate for all healthy, active men, particularly those in the armed forces, they would be less likely to satisfy the needs of all the civilians, particularly women and children. There is therefore some justification for the proposals to add iron salts to flour for civilian consumption. This is perhaps especially justified because of our lack of knowledge of the availability of iron from various foods. Iron in different organic combinations in foods certainly varies in the ease with which it may be liberated by the digestive process for absorption. No satisfactory test has yet been made for determining the availability for man of the iron in different foods. The dipyridyl method has been of some accuracy in determining iron of the food available for rats²⁸. Probably different individuals will vary greatly in their ability to absorb different kinds of food iron. The accompanying foods, the state of the gastrointestinal tract and the need of the body for iron and other metals will all influence the amount of iron absorbed from a particular food.

The Council on Foods and Nutrition of the American Medical Association has discussed adequately the enriching of flour with mineral and vitamin supplements²⁹. The problem as regards iron is that of the choice of iron preparation, the ease and efficiency of mixing, palatability, the availability of the iron and its possible detrimental effect on other constituents of the enriched flour. Obviously, the questions which this subject raises cannot all be answered even in the near future. It is fairly certain, however, that iron as a simple iron salt added to flour will be more available than the iron in close organic combination in the original flour. There is some indication, on the other hand, that iron salts mixed with other substances before feeding are less available for absorption than when fed alone³⁰. There has also been demonstrated a relationship between the utilization of iron and the amounts of calcium and phosphorus in the diet³¹ and other interrelationships will undoubtedly be established. At the present time it would appear that if whole grain flours were widely used, and the advantages of a widely chosen and adequate diet were promulgated, nutritional requirements for iron and other minerals would be adequately supplied. On the other hand, there is no definite indication that harm would result from the addition of small amounts of iron salts to flour. There is no more useful field in nutritional research at the present time than the exploration of the adequacy and inadequacy of different foods and enriched foods in supplying substances necessary to the health of man.

HEALTH ASPECTS FOR FUEL RATIONING

Donald M. Nelson, chairman of the War Production Board, on recommendation of the Fuel Oil Committee, has announced that deliveries of fuel oil will be curtailed on the Atlantic Seaboard and in thirteen Middle Western states during the coming heating season. These thirty states and the District of Columbia represent a population of more than 96,000,000 persons, but it is estimated that only about 3,140,000 oil burners exist in these states, so that the population affected is somewhat smaller than appears at first glance. A coupon rationing system has been authorized which will be administered by the Office of Price Administration. Operators of oil burners in households and apartments are strongly advised to convert oil burners to coal immediately when ever possible and not to rely on either electric or gas heating units, since both electricity and gas may be short at different times and places. The necessity for rationing fuel in the Middle West has arisen from the shortage of tankers and from the fact that oil can be drawn from producing states in the Middle West and delivered to the Eastern Seaboard to relieve the shortage there with shorter hauls than from more remote oil fields. Rationing may reduce normal winter use as much as 33 1/3 per cent, a severe winter may increase this reduction and a mild winter may ease the situation. Storm sashes, weather stripping, burner cleaning, soot elimination and improvements and adjustments of installations to cut the usual consumption of heating fuels are strongly recommended.

Supplementary rations above the average are planned for the protection of those of tender age, advanced age, the sick and those with low vitality, but Mr. Nelson warns that where conversion from oil to coal has been possible and has not been carried out, supplementary fuel rations will be denied.

The health aspects of fuel rationing as worked out by medical, public health and ventilating experts are embodied in a report submitted to the Advisory Committee, Fuel Rationing Division, U. S. Office of Price Administration, by a subcommittee headed by Leverett D. Bristol, M.D., Dr. P.H., New York. An abstract of the report of Dr. Bristol's subcommittee follows:

MEDICAL AND PUBLIC HEALTH ASPECTS OF HEATING OIL RATIONING

Physicians, engineers and public health workers are accustomed to think of indoor heating and ventilation in terms of a "comfort" zone. We may have to reorganize peacetime procedures in the direction of a "discomfort" zone. Health should not be jeopardized, any rationing plan adopted should be based on equality for all with special consideration for those of tender or advanced age, or those with actual disease or lowered vitality. Any plan must be preceded and followed through by an intelligent and extensive educational program directed by some federal agency in Washington, with whatever medical or public health assistance or leadership may be required. Centralized medical or public health advisory relationships will be of great help with state and local groups as well as at the federal level. A suggested slogan based on a popular song of the first world war is "Keep the Home Fires Burning—Low!"

In the past we have erred on the side of too high temperatures and too dry atmospheres. Temperatures

must be kept down, but we must not err at the other extreme so that severe chilling and possible sickness may result. While most of our winter ills are due to bacterial and virus infections, scientific evidence shows the important relationship of lowered resistances and changes of weather to these conditions. There is little experimental evidence to show what an individual in a wartime economy can get along without in his artificial heat requirements without injury to health.

Ventilation is not so much a matter of what we breathe in through our lungs as it is of how our skin and body react. It is more of a cutaneous than a respiratory problem. It is more immediately important to ventilate in the interest of the heat regulating mechanism of the body.

An ideal temperature irrespective of humidity and air motion, does not exist nor does a safe minimum temperature exist without these influencing factors. The following, without regard to other factors, may be considered minimum temperatures for emergency requirements of fuel oil rationing:

(a) For the average private home, 60-68 F (majority opinion 65 F)¹

(b) For the average apartment house, 60-68 F (majority opinion 65 F)¹

(c) For hospitals and sanatoriums, 68-80 F (majority opinion 70 F except operating rooms 80 F)

(d) For schools, 60-70 F (majority opinion 65 F)¹

(e) For department stores, office buildings, and so on, 60-68 F (majority opinion 65 F)¹

Indoor temperatures of dwelling places, hospitals, schools, stores and offices must vary according to the conditions and activities of occupants and the specific uses to which various rooms are put. All industries should carefully scrutinize their heating and ventilating equipment and practices to the end that winter indoor heating temperatures may be kept at the lowest possible point consistent with the efficiency of the workers.

Temperatures for department stores, it has been suggested, might be as low as 50 to 60 F dry bulb, except for the office spaces, since customers are usually dressed for outside weather and clerks could dress appropriately. For general hospital wards a minimum of 65 F and for ambulatory patients 70 F has also been suggested. Operating rooms and nurseries require higher temperatures. Consensus of authority seems to be that tuberculous patients should be treated at about the same temperatures as other hospital patients.

Thermostats should be properly adjusted and reconditioned and should be subject to the supervision and manipulation of one rather than several persons. Simple daily records of indoor temperatures should be kept even by households.

To offset reduction of customarily recommended indoor temperatures of 68 to 70 F, insulation and weather stripping are recommended. Humidification, however, in homes is regarded as relatively unimportant on the basis of recent investigations. At temperatures of 65 F or less, artificial humidification in the home is generally not necessary because laundry, bathing and living activities will result in adequate humidity for normally healthy people. Artificial humidification need be undertaken only on the specific suggestion of a physician.

Little or no attempt should be made to heat bedrooms, except those occupied by infants, aged persons or those who are ill. Bedroom temperatures may be from 50 to 60 F. The bathroom should be kept warm and a schedule set up for dressing and undressing in the bathroom. Warm night clothes and bed coverings should be provided. Living rooms should be kept at a suitable temperature at the expense of the dining room, halls and kitchen. The temperature should be lowered to 50 F at night and local heat sources should be utilized. Drafts from windows, doors and fireplaces should be minimized by keeping windows and doors closed. Pulling down window shades at night screens the cold blast from the rest of the room.

Reduced indoor temperature is less apt to injure persons in good physical condition and having good health habits. The usual recommendations relative to exercise, sunlight, food and rest are stressed. Adequate clothing, and especially foot covering, is emphasized. Cold baths of short duration are recommended for certain persons. Overfatigue should be avoided.

Indoor comfort and health depend on individual adjustments of clothing as much as on proper heating and ventilation. Double comfort standards between men and women are due largely to differences in dress or clothing. The application of this knowledge to individual situations would do much to prevent dissatisfaction and possible ill effects of cooler indoor temperatures and drafts during the winter. Every individual should be brought to realize that he is his own clothing engineer and that a heavier dress or suit, an extra undergarment or overgarment may do much toward winter health and comfort in overcool rooms. "Wear a sweater and help win the war!" The body adjusts itself readily to temperatures at least 10 degrees below what we in the United States consider the standard temperatures for dwelling houses. The English, based on experience with radiant heat, believe that a 60 F dry bulb temperature is adequate if room occupants are properly clothed.

Where coal or gas stoves or heaters are used the dangers of possible asphyxiation, poisoning and fire accidents are pointed out.

Fuel rationing must take into consideration the need for hot water if heated by oil, especially in the household where bathing and the sanitary washing of dishes and other utensils used in common must be carried out.

Dish washing devices for hand washing require a temperature of 110 to 120 F, a temperature which can be withstood by the hands. Utensils should be rinsed in hot water of not less than 170 F according to most local codes. The pouring of boiling water over washed utensils is not adequate for disinfecting purposes unless done over a period of at least one minute. In place of hot water for disinfecting purposes a warm chlorine solution (100 to 200 parts per million) may be used, about the same time period as mentioned being observed. In machine washing the temperature of the soapy wash and the rinse water should not be less than 170 to 180 F for two minutes or exposure to live steam in a closed compartment for at least five minutes.

Supplemental fuel oil should be allowed to homes in which there are children under 4 years of age, for whom a temperature of not less than 70 F should be provided.

¹ Subject to local regulations or codes

This would also take care of the needs of the nursing mother. After the fourth birthday, normal children need a cooler and not a warmer environment than adults. Older people, particularly those of lowered vitality, should have a temperature of not less than 70 and possibly as much as 74 F. Consideration should be given to individual differences, some people are "old" at 55, others are "young" at 70. In general, supplemental rations should be made available for homes with 1 or more occupants over 65. Where there are 1 or more cases of acute or chronic illness or invalidism, the physician should be the judge of the need for supplementary fuel oil rations.

The physician's place in administration and certification would consist in certifying to the ration board for the supplemental fuel oil rations for cases involving actual needs arising out of sickness and the infirmities of old age or other special cases. It might be desirable to have a local physician as a consultant or adviser to local ration boards. Consideration should be given to possible periods of abnormally cold weather and the possible occurrence of epidemics or threatened epidemics of disease and to communities which may accurately be described as health resorts.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER, Secretary

GOSZTONYI (MODEL "D") ULTRAVIOLET APPLICATOR ACCEPTABLE

Manufacturer: Ultra Rays, 1166 Highland Road, Sharon, Pa.

The Gosztonyi Lamp is essentially a low vapor-pressure "cold" mercury arc in a fused quartz burner shaped for contact application of ultraviolet radiation principally of the wave band 2,537 angstroms. About 93 per cent of the total ultraviolet output is in the wave band 2,537 angstroms according to evidence submitted by the firm. The D shaped burner is of quartz tubing about 15 mm in diameter, the straight side of which may be rubbed over or held close to the infected area. The applicator operates on 30 milliamperes in the tube and consumes about 40 watts from 110 volts, 60 cycle alternating current lines. The output of the short ultraviolet measured at 6 inches from the burner (D shaped applicator operating on the highest intensity step) was found by the firm's investigator to be 422 microwatts per square centimeter.

Gosztonyi Model D Ultra violet Applicator

The generator for the apparatus is contained in a carrying case. On the instrument panel are an "off-on" switch, a three stage rheostat and plugs for attaching the applicator. The device is arranged for use with an automatic timer.

In the Council's investigation of the device, radiometric measurements were made on the ultraviolet output of wave length 2,537 angstroms at a distance of 15 cm (6 inches) from the front edge of the straight side of the D shaped burner. The lamp was operated on 110 volts alternating current 60 cycles, on the three rheostat settings ('1, 2, 3') or approximately 10, 20 and 30 milliamperes. The corresponding ultraviolet intensities were 68, 125 and 175 microwatts per square

centimeter. The latter value is somewhat lower than that (422 microwatts per square centimeter) reported by the firm. However, this difference is to be expected owing to the difficulty in specifying the operating distance of the D shaped burner. The calculated intensity at the line of contact with the straight side of the D shaped burner would be much higher than the value (4,100 microwatts per square centimeter) given by the firm. This form of lamp therefore meets the Council's requirements for acceptance.

The Council voted to accept the Gosztonyi Model "D" Ultra violet Applicator for inclusion on its list of accepted devices.

ALOE SHORT WAVE DIATHERMY UNIT COMMANDER MODEL ACCEPTABLE

Manufacturer: A S Aloe Company, 1819 Olive Street, St. Louis

The Aloe Short Wave Unit, Commander Model is designed for use in medical diathermy and in minor electrosurgery. It is equipped with line cord, two rectifier tubes, two power tubes, two 8 by 10 inch pad type electrodes and induction cable. The unit operates on alternating current, 110 to 125 volts.

In the Council's tests of the instruments physical characteristics the following results were obtained:

Electromotive force	115 volts
Power input	650 watts
Power output	200 watts

The final transformer temperature was within the limits prescribed by the Council.

The firm submitted evidence to support the ability of the unit to generate heat deep within the tissues. In the cuff technique the electrodes were made of a stiff resilient metal so that they embraced the thigh with a springlike action. The dimensions were 2 3/8 by 25 inches (upper cuff) and 2 3/8 by 18 1/2 inches (lower cuff). The metal strip used in the electrodes was 1 1/2 inches wide. The average distance between cuffs was right, 7 1/4 inches, left 7 1/2 inches. Average spacing was right 1 inch, left 3/8 inch. Room temperature was 74 F, humidity was about 42 per cent.

Aloe Short Wave Diathermy Unit Commander Model

When the coil technique was tested the distance between coils was approximately 1 inch. About one half inch of spacing was used to separate the coil from the skin. The average thigh circumference was about 19 1/4 inches. The room temperature was approximately 75 F, the humidity was around 48 per cent.

Temperature Observations

Cuff Technique			
Deep Muscle		Rectal	
Initial	Final	Initial	Final
97.3	107.3	99.0	99.2
Coil Technique			
Deep Muscle		Rectal	
Initial	Final	Initial	Final
98.7	105.7	99.7	99.8

The apparatus was tried out clinically by a qualified investigator, who reported that it gave satisfaction when used for cuff and coil technique.

The Council on Physical Therapy voted to accept the Aloe Short Wave Diathermy Unit, Commander Model, for inclusion on its list of accepted devices.

BORG PRONE PRESSURE TIMING DEVICE
(For Instruction in Manual Resuscitation)
ACCEPTABLE

Manufacturer The Borg-Erickson Corporation, 496 East Ohio Street, Chicago

The Borg Prone Pressure Timing Device is a small platform scale measuring 10 by 8 by $2\frac{1}{2}$ inches designed for use in instruction of the prone pressure method of resuscitation. Although this device, as a scale, does not come strictly within the Council's purview as a therapeutic or diagnostic instrument, the Council is of the opinion that consideration should be given to it because of its value as a training apparatus for the manual method of artificial respiration.

The manufacturer makes the following statement: First, distinguishing red marks on the dial face indicate both the pressure (35 to 45 pounds) and Schafer's suggested (Red Cross First Aid Handbook, page 113) maximum limit (60 pounds). Second, the oscillating cycle (return to stabilized zero point) of the unit is so constructed that when the hands are removed from the platform the time required for this operation is practically the best required for proper pressure application (Red Cross First Aid Handbook, page 110, paragraph 5).

The manufacturer of this device recommends the following method for training: Place the scale on the floor at approximately 8 inches from the surface (using books or a fixture to achieve the proper height), then have the trainee assume the proper position for prone pressure application. The trainee is then to simulate the motions of the applications, using the platform as a substitute for the patient. After several demonstrations of this kind the trainee may apply the same rhythm and force on the subject. A torso replica made of paper mache may be used if desired.

In the Council's examination of the apparatus it was found to be a neatly constructed platform scale. The dial is divided to read to 250 pounds weight or force exerted against the platform. It is sensitive to less than $\frac{1}{2}$ pound and will register the same reading to a weight placed at any point on the platform. It is accurate to ± 1 pound.

When placed at a height corresponding to body thickness and pressure exerted against it, the instrument will register the maximum pressure applied at any given point. The dial is marked with two red stripes, the narrower with the midpoint at 25 pounds and the wider with the midpoint of 50 pounds. These mark the minimal and maximal pressure recommended for the Schafer prone pressure method of artificial respiration, and the limits correspond very closely to requirements of the Red Cross First Aid Handbook.

The device was tested by the students in the medical classes of an educational institution and by five members of the staff of the department of physiology. Among these were eight men who had taken Red Cross first aid class instruction, and without exception every one found that he had exerted pressure far in excess of the prescribed maximum, to the effect that several of the subjects were tender for several days.

To say, however, that 60 pounds pressure is the upper limit necessary or that 30 pounds would never do harm is quite impossible in the light of available evidence. Certain subjects with certain anatomic and pathologic variations may have little or no exchange when 60 pounds pressure is applied. Likewise a pressure of 30 pounds applied injudiciously to some slightly built individuals might conceivably fracture ribs or injure viscera. The proper pressure is enough to cause adequate exchange of air and will always be an individual consideration.

This apparatus, in the opinion of the Council, serves as a valuable training device not only in demonstrating the adequate pressure to apply but in teaching the proper concept of the rhythm and timing. The Council believes, therefore, that it

will convey to the trainee somewhere near the idea of forces and timing likely to be needed under practical conditions.

The Council voted to accept the Borg Prone Pressure Timing Device for inclusion in its list of accepted devices, provided all advertising for the apparatus is submitted to the Council for examination, that the advertising promotes the device only as an instrument for instruction of the prone pressure method of artificial respiration and that the Council seal or notice of acceptance must not appear on the scale or in the advertising for it when the instrument is promoted for uses other than as a training aid. The device is not accepted as a conventional scale for weighing purposes, nor does the Council give consideration to devices for weighing.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Acting Secretary

LIVER AND STOMACH PREPARATIONS (See New and Nonofficial Remedies, 1941, p. 328)

The following preparations of Purified Solution of Liver U S P XI for parenteral administration have been accepted: GEORGE A. BREON & COMPANY, INC., KANSAS CITY, MO.

Purified Solution of Liver, 10 U S P Units per cc
5 cc and 30 cc vials. A sterile aqueous purified solution of liver preserved with 0.5 per cent phenol.

Purified Solution of Liver, 5 U S P Units per cc
10 cc vial. A sterile aqueous purified solution of liver preserved with 0.5 per cent phenol.

Ampul Purified Solution of Liver, 2.5 U S P Units per cc
2 cc. A sterile aqueous purified solution of liver preserved with 0.5 per cent phenol, prepared by dilution of the 5 unit extract with an equal volume of sterile redistilled water.

DEXTROSE (See New and Nonofficial Remedies, 1941, p. 179)

PARKE, DAVIS & CO., DETROIT

Glaseptic Ampoule Solution Dextrose 50% W/V
10 Gm in 20 cc, 25 Gm in 50 cc, and 50 Gm in 100 cc. A solution of dextrose 50 per cent W/V in distilled water.

THEOPHYLLINE WITH ETHYLENEDIAMINE-U S P (See New and Nonofficial Remedies, 1941, p. 583)

The following dosage forms have been accepted:

THE SMITH-DORSEY COMPANY, INC., LINCOLN, NEB

Tablets Aminophyllin 0.2 Gm (3 grains)

Ampoule Solution Aminophyllin 0.5 Gm (7.72 grains) in 20 cc

PYRIDOXINE HYDROCHLORIDE (See THE JOURNAL Jan 10, 1942, p. 140)

The following dosage form has been accepted:

THE SMITH-DORSEY COMPANY, LINCOLN, NEB

Tablets Pyridoxine Hydrochloride 1 mg

SULFANILAMIDE (See New and Nonofficial Remedies, 1941, p. 505)

The following dosage form has been accepted:

HINSON, WESTCOTT & DUNNING, INC., BALTIMORE

Sulfanilamide (Sterile Crystalline) 5 gram shaker-type package

SULFAPYRIDINE (See New and Nonofficial Remedies, 1941, p. 508)

The following dosage form has been accepted:

FREDERICK STEARNS & COMPANY, DETROIT

Tablets Sulfapyridine 0.5 Gm (7.716 grains)

SULFADIAZINE (See THE JOURNAL, Feb 28, 1942, p. 730)

The following dosage form has been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH

Tablets Sulfadiazine 0.5 Gm (7.7 grains)

INDUSTRIAL SUPPORT OF NUTRI- TIONAL RESEARCH

The support of research is apparently being borne more and more by industry. Studies of human nutrition often demand observations on human beings, and such research is apt to be expensive. The universities and teaching hospitals have long carried this expense without special funds. The time has already come when large scale projects, involving special equipment and facilities, can hardly be undertaken with existing resources.

Now a group of industrial firms in the food field, or in closely allied lines, has arranged for the continuous support of fundamental research in nutrition. In December 1941 an organization known as Nutrition Foundation, Incorporated, was established with headquarters in the Chrysler Building, New York. Eighteen founding firms have each agreed to contribute \$10,000 annually for five years, this sum to aid the development of fundamental research in nutrition and in the dissemination of the results of research to physicians and other interested professional groups as well as to the public. A recent announcement states that six new sustaining members have subscribed to the undertaking. There will thus be available nearly one million dollars for the support of research on nutrition during the next five years.

Already the Nutrition Foundation has made an illustrious start in the realization of its declared purposes. The foundation is guided by a scientific advisory committee composed of prominent persons in the fields of medicine and nutrition and by its food industries advisory committee, which includes research and technical directors of firms which have contributed to the organization. Sizable grants-in-aid have been awarded to thirty-six projects in twenty-two leading universities and research centers. Applicants for grants are provided with printed forms on which they are asked to indicate the nature of the problem and other pertinent information that will aid the scientific advisory commit-

tee in evaluating the project and determining whether the request can be granted.

The expressed intent of the leaders of this foundation has been that the research should not supplant the research activities of individual firms. The emphasis has been on fundamental investigations in nutrition. The problems that are being supported may be divided into those which have a direct relationship to the war and public health and those of a fundamental nature that apparently are not related to any immediate emergency. Among the problems now being investigated are the relation of nutrition to resistance to fatigue in man, the effects of environment on cell respiration, metabolism and nutritional requirements, an evaluation of methods for aiding in the clinical detection of vitamin deficiencies, a study of the relation of the state of nutrition to cellular metabolism with special reference to rheumatic fever and the problems that may be introduced by chemotherapy, and a study of dietary factors involved in the healing of bone fractures. Grants have been made also for the support of such practical studies as the development of a natural butter that may be suitable for use under tropical conditions, a study of the utilization of proteins and inorganic salts of the soybean and the effect of methods of large quantity cooking on the vitamin and mineral content of vegetables. Studies also have been supported on the metabolic fate of choline, of the determination of thiamine and the stability of this dietary essential in cereal products, and on the relationship of proteins and vitamins in nutrition.

Another important aspect of these studies according to Prof. C. G. King, scientific director of the foundation, is the provision that is being made for the training of young persons in research under the most competent leadership in American educational institutions. By reason of the broad purposes of the foundation it has been possible to make a small grant for the support of some of the work of the Food and Nutrition Board of the National Research Council. Recently the foundation announced the establishment of a new periodical to be called *Nutrition Reviews*. Under the editorship of Dr. Fredrick J. Stare of Harvard University this publication will make its initial appearance in October or November, it will be unique in that it will contain interpretative abstracts of publications in the field of nutrition and allied sciences. The journal is intended to bridge the gap between the research laboratory or clinic and the channels through which such information becomes effective. No other problem now facing the country is more important than the securing of adequate food and the recognition of the persons and places where nutritional inadequacies may exist. The foundation, through its support of fundamental research and through its publication of *Nutrition Reviews* undoubtedly will contribute importantly to the obtaining of factual information and the dissemination of facts that will aid in the progress of the present war and in the

solution of some of the many health problems that will be presented following the successful termination of the war. THE JOURNAL offers its felicitations to the new publication which now is in its period of gestation and offers its encouragement to Nutrition Foundation, Incorporated, in its efforts to accomplish the purposes for which it was founded.

GALVANIC STIMULATION OF MUSCLE FOLLOWING PERIPHERAL NERVE SECTION

About one hundred years ago a controversy, typical of many that arose in the early nineteenth century, disturbed physiologists and anatomists. They debated actively the question of the relationship between nervous tissue, particularly the spinal and peripheral nerves, and the contractile elements of muscle. Was the property of muscular contractility inherent in the muscle itself or was it derived from the nervous system? Haller, then the greatest voice in physiology, maintained after numerous experiments that contractility remained after the nerves to a muscle had been cut through. The property of contractility, according to the hallerians, was independent of the nervous system and inherent in the muscular fiber itself. Such a bold assertion could not pass in that period without immediate censure. Other learned physiologists, an influential sect called the "neurologists," maintained that contractility was a property of the nervous system itself. Although the neurologists modified their dogmatic tenets from time to time and the hallerians extended the term "contractility," neither side overwhelmed the other for many years. Frequent experiments won for the neurologists a position of some security. Muscles lose their power of contractility when deprived of nervous influence after ten days or more.

As was characteristic of the period, much paper and ink were expended in theoretical argumentation. A few observers made wise use of the experimental method. John Reid, a young lecturer on physiology in the University of Edinburgh, while at work attempting to unravel the hallerian-neurologist entanglement, made another discovery of prime importance to medicine and of far reaching significance in civil as well as military neurology. In the third of a series of experiments, Reid¹ reported his results as follows:

The spinal nerves were cut across, as they lie in the lower part of the spinal canal, in four frogs, and both posterior extremities were thus insulated from their nervous connections with the spinal cord. The muscles of one of the paralyzed limbs were daily exercised by a weak galvanic battery, while the muscles of the other limb were allowed to remain quiescent. This was continued for two months, and at the end of that time the muscles of the exercised limb retained their original size and firmness and contracted vigorously, while those of the quiescent limb had shrunk to at least one half of their former bulk and presented a marked contrast with those of the exer-

cised limb. The muscles of the quiescent limb still retained their contractility, even at the end of two months, but there can be little doubt that, from the imperfect nutrition of the muscles and the progressing changes in their physical structure this would in no time have disappeared had circumstances permitted me to prolong the experiment.

Reid noted the importance of galvanic stimulation in maintaining the nutrition of a muscle deprived of its nervous influence. Subsequently other investigators learned that galvanism is the only means at our command of stimulating muscular contraction in a completely paralyzed muscle. As early as 1841 Reid saw the clinical implication of his animal experiment, for in a footnote he wrote "The application of the results of these experiments to the treatment of certain cases of paralysis is so obvious as to require no illustration" (p. 327).

Although the value of galvanism to Reid may have been 'obvious,' its use was by no means universally adopted by the medical profession. Over the hundred years since his discovery its value has been both overrated and completely repudiated. Experiments in the last war did not completely settle the problem, but the recent work of Ernest Gutmann and Ludwig Guttmann² put a stamp of approval on the importance of inducing muscular contractions by galvanic stimulation in accelerating the return of muscle to its initial volume after reinnervation and possibly in preventing atrophy. These experimenters found, moreover, that muscles treated with galvanism showed less fibrosis and a better excitability and contractility on direct stimulation as well as a stronger reflex action than those untreated. Reid's position is thus completely upheld by Gutmann and Guttmann, and his crucial experiment, nearly lost in the dusty literature of the past, takes a new and important place in the history of medicine.

THE CHANGING CONCEPTS IN PATHOLOGY

Pathology as defined by Welch¹ is "the science as distinguished from the practice, of medicine. In a narrower and more restricted sense pathology is a study of the structural alterations produced by the disease, as revealed at postmortem examinations and during surgical operations. Pathologic anatomy is a study of these alterations, but the symptoms and the activities of the body resulting from these morbid changes belong also to pathology."

"Nobody can busy himself continually with anatomy without noticing the changes that disease produces in the body" (Virchow²). The ancient concept that dis-

¹ Welch W. H. History of Pathology. Bull. Inst. Hist. Med. 3 (Jan.) 1935.

² Virchow Rudolf. Morgagni and the Anatomic Concept (An Address Presented on March 30, 1894, to the Eleventh International Medical Congress at Rome, Italy) translated from the original German by Robert E. Schlueter and John Auer. Bull. Hist. Med. 7: 975 (Oct.) 1939.

¹ Reid John. On the Relation Between Muscular Contractility and the Nervous System. London and Edinburgh Monthly J. M. Sc. 1: 320 (May) 1841.

ease is something general, an essence which affects the organism as a whole, was completely shattered by Morgagni, who in the seventy-ninth year of his life published a condensation of a life's work in five volumes under the title "De sedibus et causis morborum per anatomen indagatis," which means 'the seats and causes of disease as revealed by anatomy.' This is a purely anatomic concept—the beginning of the science of pathologic anatomy. From the study of organs the new medicine with its anatomic orientation advanced with Bichat to the study of tissues and with Virchow to the study of cells. Virchow traced disease to its ultimate indivisible unit—the cell. Virchow's cellular pathology was the foundation for modern scientific medicine.

The pathologist formerly devoted himself largely to dissecting cadavers and carefully recording the appearances. However, great pathologists of our era have realized that the study of structure alone was insufficient. The charge that "deadhouse" pathology was concerned with discovery of new morphologic units but failed to reveal their function was, however, only partly true. Thus, while Langerhans did not have the slightest notion of the function of the particular groups of cells within the pancreas described by him, Lawrow was led to the discovery of the conduction system in the heart while investigating the structure of the auriculoventricular node in expectation of elucidating the cause of heart failure in valvular heart disease. Here is an instance which demonstrates that a discovery of a particular structure may lead directly to the discovery of its function. Claude Bernard, founder of experimental medicine, said "It is not sufficient to know the anatomy of organized elements. It is necessary to study their properties and their functions with the aid of the most exacting experiments."

The contributions to morphologic pathology by Virchow and Rokitsansky and their schools were followed by studies in pathologic etiology under the stimulus of Pasteur and Koch. Then contributions gave rise to the new science of immunology (Roux, Metchnikoff, Ehrlich, Behring and their students). "It is characteristic of science and progress that they continually open new fields to our vision," said Pasteur. Indeed, the interest in immunology was soon superseded by that in colloid chemistry, which in turn gave way to interest in hormones, only to be followed by the discovery of vitamins. Modern medicine also witnessed the renewal of interest in heredity, constitutional types and allergy.

Modern pathology is a synthesis of all these basic concepts, a happy association of the spirit of Morgagni and of Claude Bernard. With this synthesis the pathologist of today is concerned. Simonds³ in his Christian Fenger lecture states that structure is essential to the

production, liberation, distribution and utilization of energy. Structure and function are inseparably linked together. The pathologist of today, according to Simonds, views the processes of disease from three points of view. 1 He is interested in the origin and development, that is, the pathogenesis, of the structural changes and functional disturbances characteristic of each disease. 2 Having determined the structural changes, he attempts to learn how the changes alter the function of the organ and of the body as a whole. 3 He is next concerned with the adaptations which the body makes in order to carry on in spite of these structural changes and their effect on important functions. Thus modern pathology has become largely an experimental science, including in its scope the study both of function and of structure.

Current Comment

HEALTH ASPECTS OF FUEL RATIONING

On page 370 of this issue of THE JOURNAL appears a statement relative to the health aspects of fuel rationing and a brief summary of the coupon rationing plan announced by the Office of War Production in a press release.¹ The possibility that about three million homes and apartments in thirty states on the Eastern Seaboard and in the Middle West may have to be kept at reduced temperatures in the coming winter owing to a shortage of heating oil is of interest to physicians. Warmth may be required in certain circumstances for reasons of health, and physicians may be called on under the proposed regulations to certify to the necessity for supplemental oil allowances. Families in which there are 1 or more children under 4, 1 or more persons aged 65 or older and 1 or more cases of illness, convalescent persons, persons with low vitality or persons in circumstances which require the maintenance of a higher degree of room temperature than the temperatures now recommended may wish physicians to issue certificates. In the presence of a dearth of scientific information as to tolerable minimum temperatures, a medical advisory committee to the Office of Price Administration has been compelled to disregard the standard published recommendations for the comfort zone of heating and ventilation and to attempt to establish a safe zone at a lower temperature in which health could be considered adequately safeguarded and discomfort minimized. The Office of Price Administration has tentatively accepted the recommendations of the committee as set forth elsewhere in this issue. Local physicians may be called on by the local ration boards to act in an advisory and consulting capacity to the board. They may also be requested to certify to the necessity for supplemental fuel rations in excess of the standard allowance to meet the situations outlined.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

PHARMACISTS THE GOVERNMENT URGENTLY NEEDS QUININE

The War Production Board has issued a call to pharmacists throughout the nation requesting them to turn in their supplies of quinine, regardless of age, quantity or nature. All salts of quinine, quinidine, cinchonine and conchionidine are wanted. Since the supply of these medicines has been cut off and the quota for each man in our armed forces is 4 ounces a year, the need is urgent.

Domestic use of quinine and similar chemicals, except for malaria has been curtailed making it possible for pharmacists to return unopened packages to their wholesalers for credit, and their opened packages to recognized clearing houses for assay and transfer to military medical supply stores.

The Philadelphia College of Pharmacy and Science has volunteered to act as an assaying depot for any opened packages of quinine compounds that are contributed to the war effort by patriotic pharmacists. Each package received will be tested for identity and then placed in a common container with other quantities of that particular salt. Then each mass of accumulated chemicals will be assayed for strength, certified, and sent to the Defense Supplies Corporation, which will direct the shipments to proper medical authorities. The less common salts of quinine, such as the valerate and the acetate, will first be processed to quinine sulfate or hydrochloride.

Clean, presentable quantities of quinine salts quinidine, cinchonine and conchionidine are wanted. Pills and tablets are not desired at this time. Pharmacists in the Southern states, where malaria may occur, should retain enough quinine sulfate or hydrochloride to meet their demands. All other pharmacists should ship their loose stocks immediately, by parcel post to the Philadelphia College of Pharmacy and Science, Philadelphia. Unopened packages should be returned immediately to wholesalers, who will forward them to proper authorities and reimburse the sender.

Do it now! The need is great! Let there be no more Corridors or Bataans for lack of quinine to fight diseases to which our soldiers and sailors are exposed.

The War Production Board has formally authorized the college to offer this service. All packages should be addressed to Quinine Pool, Philadelphia College of Pharmacy and Science, 43d Street, Woodland and Kingsessing avenues, Philadelphia.

ARMY TAKES OVER RED CROSS-HARVARD HOSPITAL IN ENGLAND

The U S Army headquarters for the European theater of operations has announced that the American Red Cross-Harvard University Hospital in southern England has been taken over by the army and will be the central laboratory for U S armed forces in Britain. This hospital was established in 1940 and operated jointly by the American Red Cross, Harvard University and the British Ministry of Health for the study of wartime epidemics (THE JOURNAL, Aug 31, 1940, p 788, and Jan 25, 1941 p 314). Its twenty-two buildings were all fabricated in the United States, from which the sixty-six thousand pieces of fabricated building material were shipped to England to be erected by British workmen. The director of the hospital was Dr John E Gordon, professor of preventive medicine and epidemiology at Harvard University Medical School. The staff comprised ten doctors, sixty-two nurses, six technicians and eight administrative members. Secretary of War Stimson said that it was a truly splendid addition to the U S Army's medical facilities. The hospital will be turned over to the British Ministry of Health at the end of the war.

COMMITTEE APPOINTED TO STUDY ARMY MEDICAL SERVICES

At the request of Lieut Gen Brehon B Somervell, Commanding General of the Services of Supply, and Major Gen James C Magee, the Surgeon General, the Secretary of War has appointed a committee to study the medical services of the Army, the War Department announced on September 24. The purpose of the study will be to assure the personnel of the Army the best possible medical care, both in the continental United States and in overseas theaters of operations. The committee's study will help the army medical department to maintain the high standards of professional efficiency and devotion which have been the finest traditions of the American medical profession and the medical department of the Army.

The members of the committee are:

Col Sanford Wadams U S Army retired Torrington Conn.
Col William L Keller U S Army (medical corps) retired Washington D C
John Herr Musser M D professor of medicine Tulane University of Louisiana School of Medicine New Orleans
Ivarts Ambrose Graham M D professor of surgery Washington University School of Medicine St Louis
Dr Arthur Hiler Ruggles Providence R I clinical professor of psychiatry and mental hygiene at Yale University School of Medicine New Haven Conn.
I Ben Robinson, DDS dean of the University of Maryland Dental School Baltimore
Mr James Hamilton superintendent of New Haven Hospital New Haven Conn.
Louis Dublin PhD New York statistician Metropolitan Life Insurance Company
Dr Lewis H Weed professor of anatomy Johns Hopkins University Medical School Baltimore and chairman Division of Medical Sciences National Research Council
Mr Corrington Gill Washington D C (executive of the committee)

SAVING FOOD

The Bureau of Home Economics of the United States Department of Agriculture has prepared a series of charts and folders which should be available in every home. One is entitled "Fight Food Waste in the Home." The other is "Get the Good From Your Food." These, together with some previously prepared folders called "Eat the Right Food," "Food for Growth" and "Vitamins from the Farm to You" are among the most useful, scientific and constructive items thus far made available. The material is available not only in pamphlet form but also in the form of large charts and may be obtained from the Government Printing Office in Washington, D C. The charts are sold in sets of one to ten for 25 cents for each set.

AVIATION PHYSIOLOGISTS

Another class of aviation physiologists graduated on September 12 at the School of Aviation Medicine in Texas and were given certificates by the commandant of the school, Col Eugen G Reinartz, M C. The course in aviation physiology covers the theory and practical use of oxygen equipment, the effects of lower barometric pressure on personnel, the operation of low pressure chambers and the conduct of high altitude indoctrination and classification and anoxia. The list of graduates comprises members of the air corps, of the sanitary corps and the following medical officers: Lewis E Barrick, Chicago, Dale D Dickson, Letts, Ind., Vincent H Handy, East Orange, N J, and John M McIver, Cleveland.

GENERAL PATTERSON RESIGNS AS DEAN

Major Gen Robert U Patterson, U S Army, retired, who for several years has been dean of the University of Oklahoma Medical School Oklahoma City, has submitted his resignation to the board of regents of the university because of having reached the retirement age of 65.

THE SHORTAGE OF NURSES

Plans for dealing with critical shortages in the nursing field were considered at a meeting in Washington D C of the Subcommittee on Nursing of the Health and Medical Committee of the Office of Defense Health and Welfare Services. The subcommittee recommended stepping up programs for the training of nurses and the more extensive use of auxiliary workers.

Measures taken by the Royal Canadian Army Medical Corps to meet nursing shortages in Canada were described by Miss Elizabeth Smellie, matron in chief of the corps, who is in Washington at the invitation of the Army Nurse Corps. War-time nursing practices in England were explained by Miss Elizabeth Phillips, until recently associate chief nurse of the American Red Cross Harvard Field Hospital Unit, stationed in Salisbury, England.

To arrange an accelerated program for nursing classes starting this fall, the Committee on Educational Problems in War-time of the National League of Nursing was requested to outline by October 1 suggested curriculums for twenty-four, twenty-eight and thirty month periods. For high school graduates the subcommittee recommended revising the three year curriculum so that organized education will be completed in thirty months and the last six months devoted to supervised practice. For students with two to four years of approved college preparation the subcommittee proposes compressing the training period so that the student will be graduated in from twenty-four to twenty-eight months depending on previous education and her accomplishments in the school.

To promote wider use of auxiliary workers the subcommittee recommended better classification of this type of work. It proposes that a joint committee, with power to act representing the National Nursing Council for War Service and the Subcommittee on Nursing, be asked to outline the new classification. The factors to be considered are nomenclature, qualifications, salary, training and use. The joint committee will be asked to have its plan of classification ready by October 1.

MEDICAL CORPS ORDERS

Major Norman R. Booler has assumed command of the Fort Benjamin Harrison station hospital, relieving Lieut. Col. Jesse W. Bowers, ordered to Camp Breckinridge, Kentucky. — First Lieut. George H. Rodman, Billings General Hospital, Fort Benjamin Harrison, Indiana, has been ordered to duty at Camp Atterbury, Indiana. — First Lieut. Moses H. Holland, Billings General Hospital, has been ordered to a numbered hospital, Camp Rucker, Alabama. — First Lieut. Houston W. Shaw has been assigned to duty at Fort Benjamin Harrison, Indiana. — Lieut. Wilbur G. Ball, U. S. Naval Medical Reserve, has been named medical officer at the U. S. Naval Training Station for Signalmen recently opened at the University of Illinois at Urbana. Lieutenant Ball, whose home is in Bloomington, graduated from the University of Nebraska College of Medicine, Omaha.

"TOKYO" FLIGHT SURGEON AWARDED DISTINGUISHED FLYING CROSS

First Lieut. Thomas R. White, M. C., U. S. Army, was one of twenty officers and three enlisted men to be presented with the Distinguished Flying Cross recently by the chief of the army air forces. All members of this group accompanied Brig. Gen. James B. Doolittle on his famous air raid over Tokyo and other Japanese cities, April 18. Dr. White, who graduated from Harvard Medical School in 1937, accompanied the Tokyo expedition as flight surgeon.

DR. EBAUGH TO SERVE AS PSYCHIATRIC CONSULTANT

Dr. Franklin G. Ebaugh, Denver, has been granted a leave of absence as medical director of the Colorado Psychopathic Hospital and professor of psychiatry at the University of Colorado School of Medicine, Denver, for the duration of the war. He has been commissioned a lieutenant colonel and will serve as chief psychiatric consultant of the eighth service command with headquarters at Fort Sam Houston, San Antonio, Texas.

RANK INCREASED IN MEDICAL ADMINISTRATIVE CORPS

The President recently signed a law which authorizes the promotion of officers in the medical administrative corps of the army up to and including the rank of colonel. Heretofore, officers of the medical administrative corps could not be promoted above the grade of captain. The law authorizes granting retroactive pay to those officers who were recently appointed above the grade of captain before the law was enacted and whose pay above that of captain had been disallowed by the Comptroller General as a result of limitations imposed by the National Defense Act.

GENERAL METCALFE TRANSFERRED TO WASHINGTON

Brig. Gen. Raymond F. Metcalfe, U. S. Army medical corps, retired, who has been serving as surgeon with the rank of colonel at the San Francisco port of embarkation, has been transferred to Washington, D. C. for duty on the War Department Retirement Board, of which Major Gen. Malin Craig, retired, is the head. General Metcalfe has been succeeded at San Francisco by Brig. Gen. Wallace DeWitt, U. S. Army medical corps, retired, who is also serving in the grade of colonel.

NEW HEAD OF NAVY MEDICAL SCHOOL

Capt. Charles W. O. Bunker, commander of the Naval Medical School, Bethesda, Md., on September 14 was assigned to command the Naval Medical Center at Bethesda and was nominated for promotion to rear admiral. He succeeds Rear Admiral Charles M. Oman, who will become commanding officer of the Naval Convalescent Hospital, Harriman, N. Y. Capt. Paul W. Wilson has been named to succeed Captain Bunker as head of the medical school. The latter graduated at Cornell University Medical College, New York, in 1905.

MEDICAL STATION UNITS SHIPPED TO CARIBBEAN AREA

The American Red Cross has shipped twelve complete fifty-bed emergency medical station units to certain points in the Caribbean and Canal Zone areas. The units are equipped with supplies capable of administering to fifty casualties requiring hospitalization. Six of the units were shipped to Puerto Rico, three to the Virgin Islands and three to the Canal Zone. These units are similar to those sent last summer to Hawaii and the Philippine Islands.

IDAHO PHYSICIANS IN THE ARMED SERVICES

The following physicians of the state of Idaho had already joined the armed services as of July, according to *Northwest Medicine*, August 14.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S 2708 has passed the Senate, proposing to amend the Selective Training and Service Act of 1940 so as to extend the benefits of the U S Employees Compensation Act to conscientious objectors. A companion bill H R 7459, introduced by Representative May Kentucky is pending in the House Committee on Military Affairs. H R 6196 has passed the House and Senate, proposing to authorize the authorities of the Panama Canal Zone to prohibit the importation or production of narcotics in the Canal Zone.

Bills Introduced—S 2769, introduced by Senator Walsh, Massachusetts proposes to establish the rank and grade of rear admiral dental surgeon, in the Dental Corps of the U S Navy. Dental officers will become eligible for selection and promotion to this rank and grade under the provisions governing the selection and promotion of other staff officers to the grade of rear admiral. The pay, allowances and retirement for rear admiral Dental Corps will be the same as for other officers of equal rank and length of service. S 2770 introduced by Senator Walsh, Massachusetts, provides that hereafter persons who are otherwise qualified but who have physical defects which will not interfere with the performance of general or special duties to which they may be assigned may be issued appointments in the Naval and Marine Corps Reserve and ordered to active duty. H R 7568, introduced by Representative Doughton North Carolina proposes to discharge more effectively the obligations of the United States under certain treaties relating to the

manufacture and distribution of narcotic drugs, by providing for domestic control of the production and distribution of the opium poppy and its products.

DISTRICT OF COLUMBIA

Changes in Status—S 2733 has passed the Senate, proposing to amend the existing law providing for the registration of births in the District of Columbia. H R 6362 has passed the House and Senate, imposing an annual registration requirement on persons licensed to practice the healing art in the District of Columbia. The annual registration fee will be \$2, and registration must be effected during the month of December of each year.

Bills Introduced—S 2756 introduced by Senator Capper, Kansas, provides for the issuance of a license to practice osteopathy in the District of Columbia to Maria G Waksmundzka. H R 7500 introduced by Representative Randolph, West Virginia, proposes to amend section 927 of the Code of Law of the District of Columbia relating to insane criminals so as to make the section applicable to cases arising in the juvenile court and so as to authorize the commitment of criminals suspected of being of unsound mind to the Gallinger Municipal Hospital for a period not exceeding thirty days, which period may be extended by the court for good cause shown, for examination and observation by the psychiatric staff of the hospital. If after examination and observation, the staff reports that the accused is insane, the court may then cause a jury to be impaneled to inquire into the sanity of the accused.

MEDICAL ECONOMIC ABSTRACTS

A CRITICISM OF MEDICAL SOCIETY PLANS

A view of Medical Society Plans by Lewis H Pink, superintendent of insurance of the state of New York, which contains some sharp criticisms by one who is in a position to influence these plans greatly in New York State at least, but who has not been a hostile critic, is contained in the following abstract from an address by Mr Pink delivered before the Conference of National Committee on Maternal Health held at the New York Academy of Medicine on June 20.

Hospital plans have been successful not only in New York City but upstate and in many cities and states throughout the country. But the medical care plans have almost invariably proved disappointing and none of them as yet have had any distinct success. In New York City we have licensed eight medical indemnity corporations and none of them have made more than a slow and uneventful beginning. Some have become discouraged and have submitted to voluntary liquidation. Even the corporation which received assistance from the medical organizations despite the zeal of Dr Elliott, has as yet made little progress. Those in the upstate cities have done better, but that is largely because they have some affiliation with hospital plans.

The chief difficulty with the medical plan seems to be that, while it has some support from the medical societies and the profession as a whole, the idea has not made a serious impression. Apparently, while medical men realize the danger of state medicine if something is not done, they are fearful of these cooperative ventures and, in any event so far have failed to back them with sufficient enthusiasm, force and strength. The medical societies wish to prevent those types which they

do not like, but they are unwilling to sacrifice sufficient time effort and money to make those which they do countenance successful. Some of the plans have not succeeded because the doctors expected to make money out of them and these plans are not intended to be profit making nor are they susceptible to it. Some are too complicated and lack sales appeal. In other cases the physicians did not fully realize that business backing, business judgment and also some real money are necessary to start a successful venture. While results to date are anything but encouraging we in the department have not given up hope or expectation. We believe that there is real need for the medical plan and that eventually one will show the way to success.

From the very beginning it has seemed to me that medical care is very closely bound up with hospitalization. It is not a thing apart. The care of the patient before he goes into the hospital during his hospitalization and after he leaves is or should be continuous. It would seem logical that hospital plans should be permitted to provide medical services. Organized medicine feels differently and organized medicine has prevailed. It wants a strict separation of something which, it seems to me, is not easily or properly separable. The result is that, when the Associated Hospital Service of New York finds that it needs to provide surgical care in order to give proper service to its members, an affiliated medical organization is created. This means additional red tape and unnecessary expense. We have the same situation in the very strict dividing line between our fire and casualty coverages. The companies insist that we must not have comprehensive coverages in a single company and the result is that the number of companies is needlessly multiplied because fire companies establish casualty affiliates and vice versa.

While it seems to me that the tendency is shortsighted, I am willing to ride along. I realize that while the mechanics are important they are far less so than the intelligence, spirit and character of management that go into the effort. If the doctors insist that medical care be separated from hospitalization, let us have it that way, provided the medical fraternity is willing to make it a success. The professions of law and medicine have done a great deal for this country and for the world, and we must look to them for leadership in their respective fields. We do not want to make hired men of the doctors, nor do we wish in any way to lower their professional standards. On the other hand, the medical societies must realize that they must serve, first, the public and only secondarily the interest of their members. They must not be too strenuous in opposing new thoughts, new ideas and new experiments.

The recent decision of the Court of Appeals of the District of Columbia in affirming the conviction of the American Medical Association for conspiracy to violate the Sherman Anti-Trust Law should be at least a warning. The Association attempted to prevent physicians from joining a group health organization because it was not organized along approved lines. The decision points out that professional people enjoy a monopoly which in itself is a restraint on competition and aptly says "They are restraints which depend upon capacity and training, not special privilege. The people give the privilege of professional monopoly and the people may take it away."

If the medical societies fail in broad constructive leadership and are unwilling or unable to provide adequate medical and maternity care, there is undoubtedly more than a threat of state medicine. Only recently the President of the United

States recommended the extension of the social security plan to include federal health insurance, which would provide both for permanent and for temporary disability and also for hospital benefits. Even the states are getting restless and Rhode Island only about two months ago, perhaps in order to get ahead of the federal government, established a state health insurance plan known as the Cash Sickness Compensation Act.

We are constantly recognizing wider responsibility for the maintenance of the health and well being of the public and the tendency is to exercise that responsibility through government. In this country I think most of us are agreed that private initiative and cooperation should be tried and found wanting before government is resorted to. We are not as fearful of government as we used to be, but it is not the part of wisdom to lay all our burdens on government or to make any government no matter how beneficent and well meaning, too powerful and all embracing.

What is the medical profession going to do?

LIVES SAVED FOR DEFENSE

Better medical care and improved living conditions are responsible for the fact that 2,900,000 of the 26,500,000 men of ages 20 to 44 who are subject to military service are alive and subject to such service today. This is the conclusion of the Statistical Bulletin of the Metropolitan Life Insurance Company for August. About one third of the 900,000 persons at the age of 65 are alive at the present time because of the advances of science and the standards of living that have aided in the reduction of mortality since their birth.

WOMAN'S AUXILIARY

Florida

The Woman's Auxiliary to the Duval County Medical Society held its annual meeting in the home of Mrs. Lucien Dyrenforth. The following officers were elected for the coming year: president, Mrs. Raymond King, reelected, vice president, Mrs. Ernest Veal, secretary, Mrs. Leo Wachtel, and treasurer, Mrs. W. H. McCullagh, reelected. Otis Owens of the United States Secret Service showed a talking movie "Know Your Money," sponsored by the government in a drive against the passing of counterfeit money.

Kansas

The Woman's Auxiliary to the Sedgwick County Medical Society held a luncheon in Wichita recently with Mrs. O. A. O'Donnell as hostess. Miss Jerry Daniels of Wichita spoke on "My Experience in Pearl Harbor." The auxiliary has contributed 400 garments to the Red Cross and bundles to the Committee for Relief of Disaster in that county.

Dr. W. W. Bauer of Chicago, director of the Bureau of Health Education of the American Medical Association, spoke in Salina at the high school, at Marymount College and to the Saline County women's auxiliary, which sponsored his appearance in Salina.

Michigan

At a meeting of the auxiliary to the Kalamazoo Academy of Medicine, a report was made that two more wheelchairs have been reconditioned, making a total of three which the auxiliary has given the Loan Closet to be used in the county when needed. Miss Margaret Linsell, county home demonstration agent, addressed the auxiliary on nutrition.

The Kent County medical auxiliary was addressed by Mrs. Mary Riste, dietitian at Butterworth Hospital, on "Nutrition in Relation to Defense."

The auxiliary voted to cooperate, under the leadership of Mrs. William L. Rodgers, chairman of Red Cross Nutrition Committee, with the Grand Rapids Home Economics Association and the staff of the public museum in the production of a nutritional display to be used for educational purposes. The subject for the high school essay contest sponsored by the auxiliary is "Building Bodies for Defense."

Mrs. Leiland M. McKinlay recently entertained the group with an illustrated talk on Nova Scotia, Cape Breton Island and the Marine coast. The Medical and Surgical Supply Committee is raising money with which to purchase a medical kit. The auxiliary voted to assess each member \$1.

The annual spring tea was held in the home of Mrs. Leon Devel on April 8. The program was an amusing playlet, "To—the Women," presented by Mrs. John R. Baker and Miss Millicent McElwice. Music was provided by Mrs. David B. Davis.

To each of the babies born to the members of the society during the current year a \$1 bank account was presented. There were fifteen recipients.

Minnesota

Mrs. Raymond J. Iosewski of Stillwater was elected president of the Minnesota women's auxiliary at the annual meeting, June 29-July 1, in Duluth. Other officers elected are: president elect, Mrs. F. S. McKinney, Minneapolis, first vice president, Mrs. Neil Dunbar, Northfield, second vice president, Mrs. W. N. Graves, Duluth, third vice president, Mrs. L. P. Howell, Rochester, recording secretary, Mrs. E. V. Goltz, St. Paul, treasurer, Mrs. Henry Quist, Minneapolis, auditor, Mrs. J. A. Thibes Sr., Brainerd, and historian, Mrs. O. B. Fessenmaier, New Ulm. Honorary membership was conferred on Mrs. James Blake of Hopkins because of her outstanding service to the state and national auxiliaries. The annual meeting and luncheon were held at the Northland County Club. George S. Corfield, professor of geography at the Duluth State Teachers College, talked on "Lands of the New World Neighbor." Mrs. Frank N. Haggard of San Antonio, Texas, president of the national auxiliary, was a guest at the round up breakfast on Wednesday morning.

At a recent Health Day Program given at the Mayo Foundation House with the Altruistic Club of Rochester, the auxiliary to the Olmsted-Houston-Fillmore-Dodge Counties Medical Society was addressed by Dr. R. M. Wilder and Miss Mary Foley. About 100 women were in attendance.

Medical News

(PHYSICIANS WILL CONTRIBUTE A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS REFLECT TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Physicians Needed—The Los Angeles County Civil Service Commission announces positions in the Olive View Sanatorium as physician and assistant physician, both in the field of tuberculosis. Physicians who have completed one year of internship in an approved hospital may file an application for the position of assistant physician. Doctors with one year's recent experience in the practice of medicine may apply for the physician position. Qualified persons over 55 may file for the position of physician for "duration" appointments. Applications for these positions should be made on or before October 13. The commission also announces the position of resident physician open in the Los Angeles County General Hospital in the specialties of anesthesiology, dermatology and syphilology, general medicine, neuromedicine, neurosurgery, ophthalmology, orthopedic surgery, otorhinolaryngology or pathology. Interested persons should obtain information from the commission, room 102, Hall of Records in Los Angeles, on or before Saturday, October 17.

COLORADO

Preventive Medicine Clinic—The establishment of a preventive medicine clinic by the University of Colorado School of Medicine, Denver, was announced on August 30. The report indicated that the clinic would be operated through the collaboration of the Junior League of Denver, Colorado General Hospital, Colorado Psychopathic Hospital and the medical school. Under the agreement between the Junior League of Denver and the university's board of regents the range of work of the clinic will include comprehensive health examinations for industrial and other employee groups, students and indigent patients, physical, social and industrial rehabilitation, and clinical facilities to aid in teaching medical and nursing students aspects of industrial medicine and individual rehabilitation. Newspapers reported that support for the clinic will be obtained by annual contributions from the Junior League and several industrial concerns. The project, which will offer opportunities for volunteer service by league members, will be housed in the Verner Z. Reed clinics of the medical school's outpatient department with a committee of three league members and three representing the school and hospitals supervising. Dr. James J. Waring, Denver, chairman of the clinic committee representing the medical school and hospitals, will be clinic director and Dr. Frank C. Golding, Denver, will be his assistant. Consultants will include Drs. Edward R. Mudge, professor of public health and laboratory diagnosis, and Donald E. Cummings, B.S., director of the medical school's division of industrial hygiene and associate professor of medicine.

CONNECTICUT

Follow-Up of Acute Poliomyelitis Cases—The division of crippled children of the bureau of child hygiene, state department of health, conducted a survey of every reported new case of acute anterior poliomyelitis occurring within the state during the period Jan. 1, 1941 to December 31. The object was to offer services to children with the disease and to secure information for the state register of crippled children. One hundred and thirteen new cases of poliomyelitis were reported by local health officers to the state department of health. Of these 2 were subsequently found to be erroneously reported, 1 being a case of brucellosis, the other meningitis. Of the 111 actual cases of poliomyelitis reported during this period 102 were of persons under 21 years of age and 9 of persons over 21 years of age. Of the 102 patients 3 were children with out of state residences who were in Connecticut when they contracted the disease. Of the patients having complete follow-up, 3 were out of state residents and 9 were over 21 years of age. The cases were distributed throughout fifty-four towns and cities. Bridgeport and Hartford had the greatest number of cases, 14 and 9 respectively. Excluding those patients whose homes were out of the state and those over 21 years of age (all of whom were not eligible for listing on the state register), 79 out of 99 under 21 years of age and residents of Connecticut were followed up completely. Twenty-one of 79 patients were reported as having no residual weakness, 50 were left with residual paralysis and 1 died. Of the 57 patients with residual weakness, 17 were under the care of the division of crippled

children as of Dec. 31, 1941. Twenty-four were under care in other clinics. In June 1942 the number of 1941 cases of poliomyelitis under care of the division of crippled children was 17 (an additional 4 cases having been closed, 3 as cured and 1 because the parents refused further treatment). Two cases reported shortly after the acute phase as presenting no residuals were later seen at a state crippled children clinic and demonstrated some weaknesses not noted earlier. An analysis of the state register of crippled children, representing 1,839 cases as of Jan. 30, 1940, revealed 12 per cent, or 220 cases, to be due to poliomyelitis.

DELAWARE

State Medical Meeting in Dover—The one hundred and fifty-third annual session of the Medical Society of Delaware will be held at the State House, Dover, October 13 under the presidency of Dr. William Marshall Jr., Milford. The following will speak:

Col. Arthur P. Hitchens, Philadelphia, U. S. Army, Influences of Tropical Diseases.
Col. Henry van Zile Hyde, New York, U. S. Public Health Service, Civil Emergency Service.
Capt. Richmond C. Holcomb, Upper Darby, Pa., U. S. Navy, War Cases.
Capt. Robert H. Lowe, New York, U. S. Army, Transition.
Dr. George H. Gehrmann, Wilmington, Industrial Medicine.
Dr. William Oscar LaMotte, Wilmington, Primary Glaucoma, Etiology, Symptom, Diagnosis.
Dr. Mesrop A. Terimianz, Tarnhurst, War Neuroses.

Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will also address the session on "American Medicine and the War."

DISTRICT OF COLUMBIA

Examinations of Society's Members—On August 4 the committee on public health of the Medical Society of the District of Columbia directed a communication to the society calling on members to demonstrate their belief in periodic health examinations by cooperating in a program to have examinations themselves. An announcement in *Medical Annals* for September states that eighty-five physicians have indicated that they will be examined and that they might be listed at the society's office as agreeing to have annual checkups.

ILLINOIS

Advisory Committee on Tuberculosis—Governor Green recently appointed a special advisory committee to the division of tuberculosis control with Dr. Robinson Bosworth, medical director and superintendent of the Pleasant View Sanatorium, East St. Louis, as chairman. Members of the new committee include Drs. Edward K. Steinkopf, Springfield, William J. Bryan, Rockford, Kenneth G. Bulley, Aurora, David F. Loewen, Decatur, Frederick M. Mervner, Peoria, Henry C. Sweany, Chicago, and Mr. Wellington P. Shahan, Springfield, executive secretary of the Illinois Tuberculosis Association.

Wartime County Health Departments—Special wartime county health departments are now functioning in seven of the twenty-three Illinois counties which have been named as health defense zones. Units recently added under this setup are DuPage County, Wheaton, under Dr. John P. Walsh, Greenview, Morgan County, Jacksonville, under Dr. Frank E. McCord, formerly of Topeka, and Will County at Joliet, under Dr. Cecil A. Z. Sharp, Macomb. Other counties where these units are operating are Cook, Lawrence, Lee and Williamson. Their purpose is to make available locally on a full time basis the professional services of public health physicians, nurses and sanitary engineers in both the urban and rural section of the overcrowded defense areas.

Chicago

University Promotions—Dr. Morris Edward Davis, associate professor of obstetrics and gynecology at the University of Chicago School of Medicine, has been promoted to professor, and Dr. Henry Close Hesselstine has been promoted to associate professor of obstetrics and gynecology.

Society News—The Chicago Orthopaedic Society will be addressed on October 9 by Drs. Edward A. Piszczek on "Recent Studies in the Epidemiology of Poliomyelitis", Dallas B. Phemister "Local Resection and Bone Transplantation in Bone Sarcoma," and Carlo S. Seuder, "Fracture Dislocation of the Hip."

War Neuroses—The Institute for Psychoanalysis, in cooperation with the department of neuropsychiatry of Michael Reese Hospital, will offer a series of six discussions on war neuroses October 5, 7, 9, 12, 14 and 16 designed for medical officers in the armed forces, medical students, interns and house officers. The registration will be limited to fifty but the course will be reopened on demand.

IOWA

Personal—Dr Chester L. Putnam, Manchester, has been appointed director of local health services for the state department of health effective September 1. Dr Putnam succeeds the late Dr Marvin F. Haygood, Des Moines.

Sister Kenny Honored at Opening of Unit—A testimonial dinner for Sister Kenny at the Fort Des Moines Hotel recently was a feature of the opening of the new hospital pavilion for the treatment of infantile paralysis. Drs. John F. M. Pohl and William A. O'Brien, Minneapolis, were guests with Sister Kenny at the opening of the unit, which is to be known as Kenny Cottage. Drs. James E. Dyson and Dwight C. Wirtz, Des Moines, established the pavilion under the auspices of the Iowa Lutheran Hospital.

MICHIGAN

Physical Hardening Program—The board of regents of the University of Michigan, Ann Arbor, has approved a physical hardening program which will be compulsory for all men students when the fall term opens on October 5. Formerly the program was compulsory only for students who had joined one of the enlisted reserve programs or were registered under the Selective Service System. The men students will be required to participate in three ninety minute sessions each week with the emphasis on calisthenics, obstacle races, swimming and a variety of competitive activities designed to produce physical fitness. All students taking the course undergo physical examinations and the activities in which they engage are determined by the physician's report.

MINNESOTA

New Health Directors—Dr. Herman H. Hartig has been appointed acting director of hygiene and health education of Minneapolis. Dr. Arthur E. Karlstrom, who has been director since 1940, has resigned to devote his entire time to private practice. Dr. Mario McC. Fischer, health officer of Duluth, has been appointed medical director of St. Louis County. He will serve part time and will continue his duties as city health officer.

University News—New appointments to the full time staff of the Students' Health Service at the University of Minnesota, Minneapolis, include those of Ramona L. Fodd, Ph.D., and Dr. Myron M. Weaver, director of the health service at Knox College, Galesburg, Ill., and former director of the health service at Carleton College, Northfield. Dr. Lawrence R. Boies, Minneapolis, was recently promoted from clinical associate professor in the division of otology, rhinology and laryngology to clinical professor and director of the division at the University of Minnesota Medical School, Minneapolis.

MISSOURI

Tuberculosis Medal—Mr. A. W. Jones, secretary-treasurer of the Mississippi Valley Conference on Tuberculosis and executive secretary of the Tuberculosis and Health Society of St. Louis, was presented with the Hoyt E. Darrholt Memorial Medal during the annual meeting of the conference in Chicago, September 17. Mr. Jones is one of the founders of the conference and served as its president in 1915. He has been secretary-treasurer since 1932.

MONTANA

Plague Infection—Plague infection has been reported proved in 2 specimens from ground squirrels (*Citellus columbianus*) collected in Beaverhead County, as follows: July 14 in a pool of 17 fleas and 5 ticks from 25 ground squirrels taken 15 miles northwest of Wisdom, on the north fork of the Big Hole River; July 15 in tissue from 1 ground squirrel taken 3 miles northwest of Big Hole Battlefield on Trail Creek.

Personal—Dr. Lumsford D. Fricks, Seattle, has been appointed health officer of the Helena and Lewis and Clark counties health unit, succeeding Dr. Leo F. Hall, Helena, who has resigned on account of ill health. Dr. James W. Craig, Circle, was recently elected president of the Montana Public Health Association. Miss Leila McDonald, Missoula, is vice president and Dr. Burton K. Kilbourne, Helena, secretary.

NEW JERSEY

Personal—Robert P. Fischel, Ph.D., Trenton, secretary and chief chemist of the state board of pharmacy and chief of the medical and health supply section, Office of Civilian Supply, War Production Board, received the honorary degree of doctor of science from Rutgers University, New Brunswick, at the recent commencement.

Community Home Project Quarantined for Infantile Paralysis—The seven hundred home community of Winfield, erected as a defense housing project for workers in the Kearny war plants, was under quarantine, September 9, following the death of a boy in the Muhlenberg Hospital, Plainfield, the third death in an outbreak of infantile paralysis. Under the quarantine the men will be permitted to travel between their homes and their places of employment, but children will be confined to the premises. Visitors will not be permitted to enter the homes of the men. Volunteer policemen and firemen will serve as quarantine guards.

NEW YORK

Hospital News—The Potts Memorial Hospital, Livingston, has changed its name to the Potts Memorial Institute Inc., the better to connote its services as a tuberculosis institution. The Woman's Christian Association Hospital of Jamestown will receive more than \$133,000 from the estate of Miss Stella Beatrice Lowry. Miss Lowry's will directed that the fund be used so far as possible to establish a convalescent ward for poor patients. Her mother was a founder of the hospital.

District Meetings—Among others, Dr. Louis H. Bauer, Hempstead, discussed 'Aviation Medicine' before the Third District Branch of the Medical Society of the State of New York at its meeting in Albany, September 17. The Fourth District Branch was addressed, among others, September 18 by Lieut. Col. William V. Cone, Montreal, Canada, on 'The Place of the Special Hospital in War and Some Experiences with One'. At a meeting of the Fifth District Branch in Rome, September 24, the speakers included Dr. Leon E. Sutton, Syracuse, on 'The Problem of Healing in Large Deep Burns'. The Seventh District Branch was addressed at a meeting in Rochester, September 23, among others, by Drs. Nolan D. C. Lewis and Cornelius P. Rhoads, New York, on 'The Psychological Problems of Age and Modern Conception and Treatment of Cancer'. Speakers at a meeting of the Eighth District Branch in Batavia, October 1, included Dr. William D. Stroud, Philadelphia, on 'Cardiac Pain'.

New York City

Fund for Research in Bacteriology—The New York Academy of Medicine announces that \$1,000 is available for assignment this year under the Louis Livingston Seaman Fund for furtherance of research in bacteriology and sanitary science. The committee of the academy administering the fund will receive applications either from institutions or from individuals up to November 1. The fund will be expended only in grants in aid for investigation or scholarships for research in bacteriology and science. It may be used to secure technical help, and in publishing original work or for the purchase of necessary books or apparatus. All communications should be addressed to Dr. Wilson G. Smilie, chairman of the Louis Livingston Seaman Fund, 1300 York Avenue.

Annual Graduate Fortnight—The fifteenth annual graduate fortnight of the New York Academy of Medicine will be held October 12-23. 'Disorders of the Nervous System' will be the theme of the morning panel discussions, afternoon hospital clinics, evening addresses and scientific exhibits and demonstrations which will make up the program. Dr. Timothy Leary, Boston, will deliver the Ludwig Kist Lecture Monday on 'Pathology of Head Injuries' and Dr. William V. Cone, Montreal, Canada, will give the Wesley M. Carpenter Lecture Tuesday on 'Principles of Treatment of Penetrating and Penetrating Wounds of the Brain'. Evening lectures will be given by:

- Dr. Derek F. Denny Brown, Boston, Principles of Treatment of Closed Head Injuries
- Dr. Eli Jefferson Browder, Subdural Hematoma (and Other Late Results of Head Injury)
- Dr. Edward A. Strecker, Philadelphia, Military Psychiatry
- Dr. Harold G. Wolff, The Emotions and Disease
- Dr. Donald Munro, Boston, Tidal Drainage and Cystometry in the Treatment of the Bladder in the Presence of Spinal Cord Injuries
- Dr. Joseph E. J. King, Diagnosis and Treatment of Brain Abscess
- Dr. Gilbert Horrax, Boston, Differential Diagnosis and Prognosis of Brain Tumors
- Dr. Frank B. Walsh, Baltimore, Certain Abnormalities of Ocular Movements: Their Importance in General and Neurologic Diagnosis
- Dr. Byron P. Stookey, Wounds and Injuries of the Spinal Cord
- Dr. Francis C. Grant, Philadelphia, Surgical Treatment of Pain
- Dr. Stanley Cobb, Boston, Speech Disorders and Their Treatment
- Dr. Tracy J. Putnam, Multiple Sclerosis and Encephalomyelitis
- Dr. Charles D. Aring, Cincinnati, Limitations of Vitamins in Neurology
- Dr. Nolan D. C. Lewis, Present Status of Shock Therapy
- Dr. Walter Freeman, Washington D. C., Prefrontal Lobotomy
- Dr. Lawrence S. Kubie, Types of Psychotherapy and Indications for Them
- Dr. Henry Alsop, Riley, Migraine and Other Forms of Headache
- Dr. William G. Lennox, Boston, The Prevention and Treatment of Convulsive Disorder

Morning panel discussions will cover poliomyelitis, psychoneuroses of the war, vitamins in disorders of the nervous system and psychotherapy. The clinical sessions will be held at various hospitals throughout the city. Exhibits will demonstrate recent advancements in the etiology, pathology, diagnosis, prophylaxis and treatment of disorders of the nervous system and will consist of charts, graphs, photographs, motion pictures, roentgenograms and specimens. A special exhibit of fresh pathologic material will be presented.

Refresher Course in Cardiovascular Diseases—A course in cardiovascular diseases will open October 28 under the auspices of the New York Academy of Medicine and the New York Heart Association. Dr. Clarence E. de la Chapelle will give the first lecture, on "Management of the Acute Episode in Coronary Occlusion." Other lectures in the series will be:

- Dr. Robert L. Levy: Management of the Patient from Acute Coronary Occlusion, November 25
- Dr. William Goldring: Management of Hypertension, December 23
- Dr. Edwin P. Maynard Jr.: Brooklyn Management of Cardiovascular Syphilis, January 27
- Dr. Harry Gold: Management of Heart Failure, February 24
- Dr. Irving S. Wright: Management of Peripheral Vascular Disease, March 24
- Dr. Currier McEwen: Management of Rheumatic Fever, April 28
- Dr. Arthur C. DeCraff: Management of Cardiac Arrhythmias, May 26

PENNSYLVANIA

Fifty Years in Practice—Five physicians who have completed fifty years of medical practice in Pennsylvania were given certificates September 9 at a luncheon of the Second Councilor District of the Medical Society of the State of Pennsylvania. The physicians were Drs. Margaret Hassler Reading, Neri B. Williams, Perkins, Philip Jusolin, Chester, Thomas F. Branson, Rosemont and Joseph Howard Cloud, Ardmore.

Philadelphia

Annual Postgraduate Institute—The theme of the eighth annual postgraduate institute of the Philadelphia County Medical Society will be "Treatment of Medical Emergencies." The session is planned for April 27-30, 1943.

Personal—Announcement is made of the death of Mr. George B. Johnson, secretary of the F. A. Davis Company. He was associated with this firm of medical publishers for nearly sixty-two years. Mr. Johnson died on September 7.

UTAH

State Medical Election—Dr. James P. Kerby, Salt Lake City, was named president-elect of the Utah State Medical Association at its annual meeting in August and Dr. Louis E. Viko, Salt Lake City, was inducted into the presidency. Dr. Charles Leo Merrill, Salina, was chosen honorary president for this year. Other officers are Drs. David P. Whitmore, Roosevelt, Henry C. Stranquist, Ogden, and Oscar W. French, Coalville, vice presidents; Dr. Edward S. Pomeroy, Salt Lake City, was reelected treasurer; Dr. David G. Edmunds, Salt Lake City, is the secretary; and Mr. W. H. Tibbals, Salt Lake City, the executive secretary. The house of delegates voted its advice to the continuing committee of the Rocky Mountain Medical Conference to postpone the next meeting of the five state conference for the duration of the war and informally recommended that funds of the conference be invested in war bonds.

VIRGINIA

Changes Urged in Pneumonia Program—The state epidemiologist has made certain recommendations for the pneumonia program to be carried on in the state during the coming year based on a study of the work since it was initiated in 1940. The report suggests that only ten of the thirty-nine laboratories in the state should be kept stocked and closely supervised as typing stations. The recommendation was based on the fact that eighteen of the thirty-nine laboratories made no report of any sort last year and seven others did no laboratory work. It was urged that physicians should be better informed on the advantages of the services at the typing stations and that certain counties where pneumonia is prevalent be selected and used as experimental counties where the drugs would be distributed to all physicians. The study of case reports to evaluate the program and the establishment of immunization clinics for whooping cough to prevent the pneumonia deaths often complicating whooping cough in children were also suggested. The report has been approved by the pneumonia commission of the state medical society. When the

pneumonia program opened in October 1940, thirty-nine laboratories, including the state laboratory in Richmond and its branches in Norton and Luray, were selected so that one was within 25 miles of every physician in the state and authorized to do typing, blood work, urinalysis and sulfapyridine determinations on indigent patients. When the physicians request card and a report of the laboratory work had been sent in the laboratory was reimbursed by the state up to \$10 per patient. Excluding the work done by the Medical College of Virginia, which is a consultant for the program and under contract to do all work sent to it \$1,184.50 was paid out to the laboratories in a period of eight months, Oct. 1, 1940 and June 30, 1941. This paid for laboratory work on 209 indigent patients at an average cost of \$5.67 per person. In the next ten months, July 1, 1941-April 30, 1942 only \$515 was paid to these same laboratories for work on 94 indigent patients. Analysis of the work revealed that these figures represented an approximately equal decrease in each laboratory test rather than an excessive decrease in any particular one. If those who were only given the drug are added to these figures 381 were cared for during the first period and 144 in the second. The total figures for the Medical College of Virginia show the same decrease 179 patients the first period and 94 the second.

WASHINGTON

Personal—Dr. William L. Jackson, Burlington, has been named health officer of Skagit to succeed Dr. William V. King Jr.—Dr. Guy W. Kennicott has resigned as health officer of Chelan.

Society News—Dr. Walter C. Alvarez, Rochester, Minn., addressed the Pierce County Medical Society in Tacoma September 22 on "Puzzling Types of Abdominal Pain."—The recent annual meeting of the Tacoma Surgical Club was addressed by Dr. Leo Eloesser, San Francisco, on "Fractures in War Time" and "Trauma of the Lung."

Special Lecture Series—Dr. Hans Lissner, clinical professor of medicine, University of California Medical School, San Francisco, gave a special group of lectures in Seattle September 26 under the auspices of the University of Washington Extension Course, King County Medical Society and the Seattle Academy of Medicine. His subjects were "The Indications for and Methods of Administering Male Hormone Preparations," "Clinical Experiences with Newer Improved Female Sex Hormone Preparations" and "Obesity: Discussion of Its Problems and Management."

WISCONSIN

Marquette Discontinues Fifth Year—Because of the irregularities of graduation occasioned by the acceleration of the program of studies for the duration of the war, the executive faculty of Marquette University School of Medicine has decided to discontinue the fifth or intern year as a requirement for the degree of doctor of medicine. The present fourth year class will be graduated and receive the degree of doctor of medicine about the middle of February 1943. This change in policy necessarily brings about a change in the relationship between the university and the hospitals in which graduates will serve their internships in the future. Under the new ruling the university is asking to be released from the contract it has signed with these hospitals believing that it cannot supervise students who have already graduated. The university promises its cooperation with the hospitals however in that it will require from four year students who have contracts with hospitals that as a condition of graduation they promise on their honor to fulfill their part of the contract as perfectly as if the contract had not been changed in any way.

WYOMING

Personal—Dr. Dorsey S. Lenz, formerly of Edgerton, has been appointed health officer of Campbell County.—Dr. Philip D. Ketchum, health officer of Laramie County, was recently appointed health officer of Cheyenne, succeeding Dr. Walter S. Kotas, who entered army service.

State Medical Election—Dr. Earl E. Whedon, Sheridan, was named president-elect of the Wyoming State Medical Society at its recent annual meeting in Cheyenne, and Dr. George H. Phelps, Cheyenne, was inducted into the presidency. Dr. Roscoe H. Reeve, Casper, was elected vice president and Drs. Marshall C. Keith, state health officer, and Frederick L. Beck, both of Cheyenne, were reelected secretary and treasurer respectively. The society agreed to discontinue its annual convention for the duration of the war.

GENERAL

Dr Rhoads Awarded Caldwell Medal—The Caldwell Medal of the American Roentgen Ray Society was presented on September 16 to Dr Cornelius P Rhoads, director of the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, during the society's annual meeting in Chicago. The medal is presented for distinguished work in cancer research.

Examination in Dermatology and Syphilology—The American Board of Dermatology and Syphilology announces that a written examination will be held in various cities throughout the country on October 12. The oral examination will be in Chicago, December 4-5. Application for group A must be received by the secretary, Dr C Guy Lane, 416 Marlboro Street, Boston, by October 12.

Sister Kenny Awarded Gold Key—The gold key awarded annually by the American Congress of Physical Therapy, has been presented to Sister Elizabeth Kenny, an Australian nurse, as the person "who has made the greatest contribution to the field of physical therapy during the past year." The congress reported that the Kenny method of treating infantile paralysis at the Minneapolis General Hospital has been increasingly studied and copied by the medical profession.

Special Society Elections—Dr Kristian G Hansson, New York, was chosen president-elect of the American Congress of Physical Therapy at its annual congress in Pittsburgh in September, and Dr Fred B Moor, Los Angeles, was installed as president—Dr Joseph H Globus, New York, was recently elected president of the American Association of Neuropathologists. Other officers included Drs Harry M Zimmerman, New Haven, Conn., vice president and Armando Ferraro, 150 East Ninety-Third Street, New York, secretary-treasurer.

Awards to Chemists—The Francis P Garvan gold medal, honoring women in chemistry, was presented to Florence B Seibert, Ph.D., associate professor of biochemistry at the Henry Phipps Institute, Philadelphia, for "distinguished work on the chemistry of tuberculosis during the recent annual session of the American Chemical Society." The \$1,000 American Chemical Society Prize in pure chemistry, given annually for outstanding research in pure chemistry by a man or woman less than 36 years old, was presented to John L Oncley, Ph.D., Harvard Medical School, Boston. Dr Seibert received her degree of doctor of philosophy at Yale University, New Haven, in 1923 and Dr Oncley received his Ph.D. at the University of Wisconsin, Madison, in 1932.

Red Cross Receives Army-Navy E—The American Red Cross Blood Donor Service received the Army-Navy E award at special ceremonies in Washington, September 15. The presentation was made by Samuel Kurtz, a torpedoman who lost both legs in the torpedoing of the U.S.S. Kearny. Torpedoman Kurtz, whose life was saved by twelve plasma transfusions, raised the Army-Navy E pennant over National Red Cross Headquarters. The Army-Navy E pin was presented to Dr G Canby Robinson, Baltimore, head of the American Red Cross Blood Donor Service. Reports from representatives from eighteen blood donor centers in principal cities revealed that to date 735,759 pints of blood had been collected by the American Red Cross.

League of Nursing Education Recommends Accelerated Program—The board of directors of the National League of Nursing Education, in consideration of the great demand for graduate nurses for military and civilian services, has agreed on the following group of recommendations to meet the war emergency:

That schools offering the three year curriculum plan to complete within thirty months all organized instruction and clinical experience in at least the four major services: medicine, surgery, obstetrics and pediatrics, leaving six months free for supervised practice wherever needed in the hospital. This arrangement would also make it possible should a plan be worked out in cooperation with army and navy hospitals for students who choose to go into military service to have such an affiliation during this six months or later if the need becomes more acute. Students might be released to enter military service at the end of the thirty months.

That where state laws permit an accelerated program be planned for students admitted with two to four years of approved college preparation which would make it possible for such students to be graduated at the end of twenty-four to twenty-eight months. The length of time should be determined on the basis of the previous educational preparation of the student and her level of achievement in the school.

That schools of nursing critically examine their curriculums and eliminate duplications in instruction and nonessential activities giving emphasis to those elements in the curriculum that are most vital in terms of present and probable future needs.

That every effort be made to extend the use of auxiliary personnel in so far as this can be done with safety to the patient.

That in view of the greatly enlarged number of student nurses and auxiliary personnel in hospitals definite measures be taken to retain and stabilize teaching and supervisory staffs to provide for the adequate preparation of students and the proper supervision of auxiliary workers.

Academy of Physical Medicine—The twentieth annual meeting of the American Academy of Physical Medicine will be held at the Statler Hotel, Boston, October 14-17, under the presidency of Capt William Seaman Bunbridge, M.C., U.S. Naval Reserve, New York. The first session will be devoted to a consideration of "Physical Medicine in the Services" with the following speakers: Col Edgar Erskine Hume, M.C., U.S. Army, Carlisle, Pa., in army activities, Capt William E Eaton, M.C., U.S. Navy, Great Lakes III, in the naval hospital, Dr Charles M Griffith, Washington D.C., in the veterans administration, Dr Andre William Reggio, Boston, the role of the physician in civilian defense, Sir Robert Stanton Woods London read by Dr William D McFee, Boston, the care of the civilian casualties in England and Drs Frank H Krusen and Earl C Elkins Rochester, Minn., the teaching of physical medicine in relation to the war effort. Other speakers on the program will include:

Dr Frank H Lahey, Boston, Some Problems of Medicine in Relation to the War.
Aurl S Lion, D.Fng, Cambridge Mass, Method of Determining Dose and Local Distribution in Short Wave Therapy.
Drs. Walter J Zeiter and Albert D Ruedemann, Cleveland, Further Observations on the Use of Short Wave Diathermy in Lesions Involving the Orbit.
Dr Frank K Ober, Boston, Physical Medicine in the Treatment of Lame Back.
Francis O Schmitt, Ph.D., Cambridge, Biologic Investigation of Medical Interest with the Electron Microscope.
Robert S Harris, Ph.D., Cambridge, Appraisal of Nutritional Status in Human Beings.
Dr Herman A Osgood, Boston, The Treatment of Epithelioma by Electrosurgery and by X-Ray.

A symposium on the after-care of poliomyelitis will be a feature of the meeting on Friday with the following speakers: Drs Ober, William Benham Snow, New York, Kristian G Hansson, New York, William T Green, Boston, Mark Joseph Daley, New York and Robert L Bennett Jr., Warm Springs, Ga. Dr Winifred Overholser, Washington D.C., will deliver the Arthur H Ring Foundation Lecture Friday evening. On Saturday morning the practice of physical medicine at the Massachusetts General Hospital will be shown in case presentations covering the peripheral nerve injuries, poliomyelitis and rheumatoid arthritis.

CORRECTION

Arteriosclerosis with Diabetes Mellitus—In the article by Lisa Magidav, Galloway and Hart in THE JOURNAL, September 19, two words are transposed in the last two conclusions, page 195. They should read "arteriolar sclerosis of the kidneys" and "peripheral arteriosclerosis."

Government Services

Dr Seeger Named Industrial Hygiene Consultant

Dr Stanley J Seeger, Tarrant, Texas, chairman of the Council on Industrial Health of the American Medical Association, has been named consultant to the division of industrial hygiene of the National Institute of Health, according to *Industrial Hygiene*. Dr Seeger will maintain contact with the state and county medical societies to recruit physicians with the growing importance and demands of practice.

Census Bureau Provides Health Services for Employees

A health program providing extensive medical facilities for its employees has been inaugurated by the Census Bureau in its new building at Suitland, Md., according to the *Washington Star*. Dr Leon Schwartz of the U.S. Public Health Service is in charge. Preplacement physical examinations will be made, supplementing those required for employment by the Civil Service Commission. Illnesses or injuries that develop during the day's work will be treated. Advice will be given to employees but actual treatment will be left to the family physician. Health records will be kept for each worker, and studies will be carried on to prevent or reduce loss of time due to occupational and other diseases.

The Treatment of Malaria

In losing Java the Allies lost more than 90 per cent of the world's supply of quinine, and the treatment of malaria was made more difficult. In opening a discussion at the Royal Society of Tropical Medicine and Hygiene, Sir Samuel Rickard Christophers said that up to ten years ago the only specific drug of any distinct potency was quinine, though the other emollient alkaloids were useful. Besides these, various derivatives of the quinine type, notably hydroquinone, were considered by some to be even more effective than quinine. But it was doubtful whether the total alkaloids or any derivatives could meet the demand for efficient substitutes, and we must turn to the recently developed synthetic antimalarials, of which mepacrine and primaquine were well established. Phosphochin (which is called pamaquin in England) had the remarkable property of acting on the sexual forms of the parasite, but attempts to control malaria in communities through this action had not met with much success, though it might reduce the spread of infection in hospitals. It was more and more used as a sort of adjuvant to quinine or atabrine (which in England is called mepacrine), especially in after-treatment and so-called prophylaxis. But it was now rarely used in the acute disease because it was rather toxic and not very effective against the asexual stages of the *Plasmodium* parasite. Many considered that it had a beneficial effect in reducing liability to relapses, especially when used in after-treatment or prophylaxis with the more active schizontocidal drugs quinine and atabrine. It was not a satisfactory substitute for quinine in the acute disease.

But atabrine was generally accepted as at least as effective as quinine in the acute disease in reducing liability to relapse and in so-called prophylaxis. Since all our ideas regarding treatment have been built up on quinine, Christophers summarized present views as to this drug. We were not now so insistent in timing our doses to catch the sporulation forms but tried to ensure a sufficiency of quinine in the blood throughout the period of treatment. We now knew that the heroic doses once given were useless. We do not give more than 30 grains (2 Gm) in a day and many consider 20 grains (1.3 Gm) adequate in acute malaria. We also now knew that it was useless to try to eradicate infection by unduly long administration. About seven days' treatment was suitable to cover the period of the attack. For so-called prophylactic use there were two common methods, 5 or 7 grains (0.32-0.45 Gm) daily or 15 grains (1 Gm) on two successive days in the week. In the main these results were applicable to atabrine. We did not give more than 0.3 Gm daily in three doses of 0.1 Gm. The toxicity apparently was not great. There was liability to some gastrointestinal and nervous effects. Atabrine had a cumulative effect, so that its administration should be watched. In the acute attack it was usually given for not more than seven days and, if necessary, repeated after an interval. In prophylaxis the dosage must be cautious, 0.2 Gm on two successive days in the week or even at longer intervals. It gave rise to a yellow coloration of the skin, but this was not harmful. Atabrine had an advantage over quinine in its suitability for intramuscular injection. In the ordinary case it was best given orally, but if there were cerebral or other pernicious manifestations parenteral administration was necessary. With quinine, on the other hand, careful intravenous injection was the method. Intramuscular use was unjustified, as absorption was too slow. Moreover, a necrotic mass formed and might lead to tetanus or sloughing.

A Well Balanced Diet in Pregnancy

A medical committee appointed by the People's League of Health to investigate the nutrition of expectant and nursing mothers has for the first time obtained clear evidence of the importance of diet. A survey was made of the records of over five thousand women and is believed to be the most comprehensive ever carried out. The object was to show whether the addition of the appropriate vitamins and minerals to the daily food would have a beneficial effect on the course of pregnancy and labor and on the newborn child. In general there was no especial deficiency in the diets of first class protein, but a shortage of calcium was found in about 70 per cent of the women, most of whom were taking insufficient milk and cheese. There was a greater deficiency of iron, only 2 per cent having a satisfactory intake. There was much deficiency of vitamins. More than half of the women took insufficient vitamin A. Vitamin B insufficiency was less noticeable, the diets were not badly defective, but nearly half the women were not taking as much as was desirable. The same held for vitamin C. The committee decided on a daily supplement to the deficient diet of saccharated carbonate of iron 18 grains (1.15 Gm), calcium lactate 30 grains (2 Gm), iodine, manganese and copper minute quantities, adsorbate of vitamin B₁ 15 grains (1 Gm), vitamin C 100 mg and halibut liver oil (vitamins A and D) 6 minims (0.4 cc).

In the antepartum clinics at which the experiment was made the women were divided into two groups, of which one received the supplements and the other did not but acted as a control. The first investigation was of the toxemia of pregnancy. Cases were regarded as toxemic which showed a systolic blood pressure of or above 140 mm of mercury or a diastolic pressure of 90, with or without albuminuria, edema and so on or in which there was no hypertension and the diagnosis was based on albuminuria. In 1,530 primigravidae who received the supplementary diet the toxemia percentage was 27.1, in those who did not it was 31.7. This result was striking and indicated a protection by the supplementary diet of almost 30 per cent.

Evidence was also obtained of benefit to the infant. Of 1,529 primigravidae receiving the supplement the pregnancy ended prematurely (before the fortieth week) in 308, in 1,512 not receiving it the number was 361. The investigation was held to show the benefit to mother and child of a well balanced diet in pregnancy.

Depletion of the Staff of a Famous Hospital

The war has had a profound effect on medical service in the country. A high proportion of the doctors—practically all the younger ones—have been taken into the fighting forces. The staffs of the hospitals have been depleted. In his annual report for 1941 to the governors of Guy's Hospital, the treasurer, Lord Nuffield, referred to the large numbers of the staff, medical, nursing and lay, now on active service. He reminded the government departments concerned, and particularly the Ministry of Labor, that further depletion of the ranks of the hospital's experienced staff must react very unfavorably on the work that it was able to do. An appointments system had been introduced for outpatients whereby the interval between the patient's arrival and his examination by the medical staff had been reduced to a minimum. Guy's Hospital was playing a predominant part in the work of the busiest and most exposed of all the sectors into which London had been divided for dealing with the casualties of air raids.

Raw Vegetables in School Meals

The Board of Education has informed local education authorities that, owing to lack of fruit, particularly oranges, school meals should include a helping of raw vegetables several times a week or, if possible, every day. In the absence of fruit,

vegetables are the main source of vitamin C, but this is usually destroyed by cooking. Special efforts are to be made to introduce raw vegetables into the dietary before next winter. Authorities are advised to give about 1 ounce of salad or sliced vegetables twice or thrice a week and gradually to increase the amount to 2 or 3 ounces.

Research on Shock

Traumatic shock was studied again in France during 1940 by the medical department of the French army which organized a liaison service between the clinical observations made on the battlefield and the experimental research performed in the back areas. Antishock centers have been organized. The Comité national des recherches scientifiques has founded a committee to study shock comprising surgeons, physicians and biologists. Prof. Leon Binet, author of a book on hemorrhage, shock and asphyxia published in 1941, is an eminent collaborator of this committee. In a recent meeting of the Société des chirurgiens de Paris he gave a report of his work since 1940 performed chiefly on dogs. He has used in experimental shock the method known as histamine shock. A solution of histamine hydrochloride in a dose of 25 mg. per kilogram of body weight is intravenously injected into an anesthetized animal. The arterial tension is lowered immediately and the respiratory rhythm becomes irregular. Ten minutes after the first injection a second dose of 2 mg. is given. A bronchial spasm with collapse and dyspnea appears. Generally the animal dies if left to itself in thirty to sixty minutes. An interesting biologic phenomenon is the increase in red blood cells, contrary to the classic anemia due to hemorrhages. The number of red cells increases from 6 million (normal for dogs) to 7.9 millions. There is no evidence of mobilization of red cells by contraction of the spleen as in the case of asphyxia. In histamine shock there is a hemoconcentration by alteration of the capillary permeability, especially of the abdominal capillaries which manifests itself by an escape of water from the blood into the body tissues. The plasma leaves the blood vessels and a progressive reduction of the blood mass results. Binet gives an intravenous injection rapidly to restore fluid: 500 cc. of a solution consisting of sodium chloride 8 Gm., sodium bicarbonate 8 Gm., sodium thiosulfate 4 Gm. and distilled water to make 1,000 cc. Dextrose is not added because there is already a hyperglycemia. Sodium bicarbonate is added because there is a precocious and accentuated falling of the total carbon dioxide in the plasma. After this injection an increase in the arterial tension and disappearance of the respiratory difficulty are observed. But this improvement is only transitory in severe cases. For the very severe cases Binet follows up after the previous injection with an injection of diluted blood, that is 3 parts of serum and 1 part of preserved blood. Binet proposes the following formula for diluting the blood: distilled water 1 liter, sodium chloride 8 Gm., sodium bicarbonate 15 Gm. and sodium thiosulfate 4 Gm. This experience on a large scale with dogs led to experiments on human beings in 1940 with good results. These experiments on 150 dogs are part of a movie picture. In the meantime several surgeons, among others Professor Luguet, have obtained good results with the solution proposed by Binet.

The Present State of French Children

At a recent meeting of the Académie de médecine Jules Hubert, Colleson and Roueche of the Comité national de l'enfance (the director of which Professor Marfan died recently) reported on a survey questionnaire addressed to 463 physicians on the general mortality and morbidity, on the health of children, on nutrition in general, on vitamin deficiencies and on the frequency of tuberculosis. Among the answers were 119 from departmental inspectors, directors of boards of health,

pediatricians, physicians and medical inspectors of schools. This inquiry is still going on but it is already possible to indicate the first general trends. Mortality and morbidity are not higher in the different age periods of these children. A recrudescence of rickets is indicated. Skin infections, scabies and parasites of the hair are constantly increasing. Last winter cases of freezing and chilblains in enormous numbers occurred. Troubles of the endocrine genital functions chiefly in girls were observed. The prolonged deficiencies of protein, fat and vitamins have caused syndromes of pellagra and other diseases. Most serious, however, is the frequent appearance of miliary tuberculosis and of caseous pneumonia.

The most common complaint in these reports is the danger to children due to food insufficient in calories and lacking animal proteins and mineral salts.

At a recent meeting of the Académie de médecine H. Gounelle, A. Valette and Monc presented the results of a survey of 1,075 Paris school children which revealed that their height and weight are declining. In comparison with tables compiled in 1935 by A. B. Fessard a decrease of 1 to 5.5 cm. in boys aged 5 to 12 years and of 1.5 to 2 cm. in girls of the same age is stated. The same trend in their weight is reported.

The Effect of Food Deficiencies on the Blood

In a previous letter it was indicated that food restrictions have created new pathologic conditions in France. This new problem has been studied in various clinics and laboratories. At a recent meeting of the Académie de médecine Jean Girard, Pierre Lomoy and Marcel Verdin reported their studies of 90 persons, mostly workmen, chauffeurs, engineers, unskilled laborers and fitters who complained of progressive weakness which appeared on awakening in the morning, increased during morning hours and decreased after lunch. The accompanying vertigo sometimes gave the feeling of a cerebral vacuum and compelled the person to lean against something or sit down. This condition resulted in incapacity to work and certain patients had to go to bed. They suffered nocturnal perspiration and became very sensitive to cold even during summer. This state was accompanied by psychic depression and apathy. In several cases their relations wanted them to be interned in an asylum. Arterial hypotension was present, loss of weight and paleness of the skin without any relation to the figures for the hemoglobin or the red blood cells. All these syndromes can be ascribed to the present food shortage. Very interesting are the results of various examinations: an increase of the bleeding time, a hypoglycemia below 0.85 per cent in 70 per cent of the patients, a hyposcorbemia in 70 per cent of the patients, the vitamin C being below 8 mg., a mononucleosis in 58 per cent of the patients, an eosinophilia, an increase in red blood cells in 53 per cent of the patients and a slight anemia in 25 per cent of the patients. All these results are due to alimentary shortages. The reporters refrain from making definitive conclusions concerning the prognosis for these asthenic patients.

Smallpox

In February smallpox broke out in Paris, the first case appearing in the surgical service of the Hôpital St. Louis, the next ones in the Hôpital des Enfants Malades and in the Hôpital Bichat and then cases appeared also in town. The Académie de médecine has claimed that a general and massive revaccination should be ordered. Vaccination is obligatory in France during the first tenth and twentieth years but the law is far from being observed. A modification established by the law of 1915 states that in case of war, epidemics or threat of epidemics vaccination can be made obligatory by decree or by orders of a prefect for everybody, no matter what his age, if he has not been vaccinated or revaccinated successfully within five years. In the last claim of the Académie de médecine this delay has been diminished to three years.

An epidemic appeared in 1919 at Lyons with 912 cases and 167 deaths. In 1933 an epidemic occurred at Rouen with 21 cases. In the 1942 epidemic in Paris the disease was generally mild. Its origin has not been discovered. In the Hospital Pasteur, Louis Martin observed that, contrary to other infections, smallpox baffled all isolation measures. Only massively performed vaccinations are efficacious. At a recent meeting of the Société médicale des Hôpitaux de Paris, Haudin and Millot said that a striking effect of the present revaccination of citizens is the sensitiveness to vaccine. Positive vaccinations have been present in 70 to 80 per cent. Formerly in vaccination at schools and in the army positive vaccinations were only 20 per cent. Explaining this fact, Lereboullet and Hille maintained at this meeting that the sensitiveness is due to the greater action of the vaccine now in use. They propose to make no more than two superficial scarifications of 1 to 2 mm in length and rather distant from each other. Often one is enough. All these facts accentuate the necessity of undertaking a campaign for the general vaccination of the population.

Whooping Cough and Tuberculosis

In the Société de pédiatrie de Paris R. A. Marquezzy, Mlle M. Ladet and Minc. Cam recently reported observations in the Hôpital Claude Bernard during the years 1937-1941 in 269 cases of whooping cough in children whose cutaneous reaction to tuberculin was positive before the whooping cough. In one group are children suffering with slight tuberculosis of the lungs characterized by a positive cutaneous reaction with a radiographic picture as good as normal. Among 145 cases there was no activation of previous pulmonary lesions, although in certain cases the whooping cough became complicated with acute pneumonia. In a second group are children who had both whooping cough and active tuberculosis of the lungs. Among 53 cases 14 were fatal. The condition is extremely dangerous in cases of extensive nodular tuberculosis, but generally whooping cough and pulmonary tuberculosis seem to evolve separately.

At the same meeting Julien Marie discussed his observations made in 1941 on 555 children with whooping cough, of whom 83 also had tuberculosis. The mortality of the tuberculous was double that of the nontuberculous children.

BUENOS AIRES

Public Health in Peru

The government of Peru has increased the budget for expenses on public health to 14 per cent more than that of last year. The following national departments were recently established: an antituberculosis department with centers for the care of patients of several categories in various regions of the country, a department of epidemiology for sanitary work concerning prevention and control of epidemics as well as for the preparation of statistics and a department for work on rural sanitation and work against malaria. Attention is being given to the plan presented by John Winant, LL.D., the ex-president of the International Labor Office, who is now the ambassador of the United States to Great Britain, for waging antituberculosis campaigns. Vaccination against rural yellow fever is obligatory. It is given without any charge to persons who live in certain territories, which have been specified by the General Department of Public Health as foci of the disease. The persons living in those territories who do not want to have the vaccine and who are not immune are subject to a fine. The number of centers of the National Department against Plague, the personnel for clinical and laboratory research against plague and the number of antiplague units have increased. The work against venereal diseases is intensified

especially in the region of the port of Callao. Sanitary campaigns against endemic diseases and work for sanitation of the Peruvian selva are organized. The central laboratory of the government, which is established in the selvatic region, is in charge of the technical exploitation of many valuable plants which are of great industrial importance. The protection of mothers and children is constantly improving through the coordinated work of proper organizations, mainly the so called ambulance for infantile hygiene, the Hospital del Niño and the Instituto Nacional del Niño. The latter organization has given medical care to more than 225,000 children, lunches to more than 55,000 pregnant women, medicine, dietetic products and about 290,000 liters of milk to children, and odontologic care, vaccines against several diseases and more than 2,400,000 lunches to school children in the various provinces. Work is carried on for increasing the number of hospitals, which is insufficient. There are seventy-two hospitals with a total number of 8,636 beds in charge of the societies of public welfare. The National Department of Industrial Hygiene, which is a branch of the Ministry of Public Health Work and Social Welfare, was recently established. The department is in charge of the prevention of industrial diseases, especially in miners. However later on it will be in charge of the prevention of industrial diseases in workers in all industries in the country. The department is in charge also of sanitary control of houses of industrial workers and of administration of medical care to industrial workers.

Scientific Relations Between Argentina and Brazil

The scientific relations between Argentina and Brazil are close. Groups of physicians of each country make visits to the other country for the exchange of scientific knowledge. Books of Brazilian medicine have been recently translated into Spanish under the honorary direction of Dr. Mariano Castex, professor of clinical medicine of the Faculty of Medicine of Buenos Aires and under the active direction of Dr. Egidio S. Mizzer and Elyser Magalhães. The volumes of this collection have been translated into Spanish with the aim of enabling Spanish speaking physicians to know some of the most important books of their Brazilian colleagues. Dr. Jose Silveira's book "Atelectasia y Tuberculosis Pulmonar" is the first one of this collection to be translated. Three other books are going to be translated and published in the near future: (1) "Enfermedades del Hígado. Diagnóstico, Patología, Terapéutica," by Dr. Clementino Fraga, (2) "Aneurismas Aórticos," by Dr. A. de Almeida Prado and (3) "Propedéutica Radiológica" by Prof. Manuel de Abreu. All these books are edited by the publishing house "El Ateneo" of Buenos Aires.

Conference Against Echinococcosis

The National Conference against Echinococcosis was held in Buenos Aires in May, with physicians and veterinarians participating. Several plans for carrying on systematic study of the infection in different regions and of developing various methods for its prevention were approved. It was resolved that laboratory and clinical research be intensified in order to discover a biologic method for an early diagnosis of echinococcosis. It was also resolved to give anthelmintic therapy to any dog which is brought in to the country, even for a short time.

Crusade Against Flies

Studies are in progress in the National Department of Hygiene to discover some means against reproduction of flies. The crusade will be nationwide. Dr. John D. Long, the representative of the Pan American Sanitary Bureau of Washington, comes to Argentina once a year as a rule. He has directed the attention of the sanitary authorities on the extraordinary abundance of flies in Buenos Aires.

Deaths

Charles Howard Moore * Philadelphia, Medico-Chirurgical College of Philadelphia, 1907 specialist certified by the American Board of Orthopaedic Surgery, Inc., associate professor of orthopedics at the Medico-Chirurgical College, Graduate School of Medicine University of Pennsylvania, member of the American Academy of Orthopaedic Surgeons, consulting orthopedist to the U S Public Health Service in 1928, served as a major in the medical corps of the U S Army during World War I, for many years chief of the orthopedic staff of the Delaware Hospital Wilmington, orthopedic surgeon on the staff of St Mary's Hospital from 1923 to 1926, author of 'Knee Joint Fractures', aged 62, died September 10, in the Presbyterian Hospital.

Carl Philip Wagner * Portland, Conn. University of Nebraska College of Medicine Omaha 1928 specialist certified by the American Board of Psychiatry and Neurology, Inc., member of the American Psychiatric Association the New England Society of Psychiatry and the American Orthopsychiatric Association, assistant in psychiatry at the Columbia University College of Physicians and Surgeons New York, since 1934, at one time instructor in psychiatry at the Yale University School of Medicine New Haven, Conn., psychiatric examiner for the U S Army induction center in Hartford medical superintendent and owner of the Limerick Manor, aged 44, died, August 10, in the Hartford Hospital of coronary thrombosis.

Wallace Belding House, New York New York Homeopathic Medical College and Hospital New York 1899 emeritus professor of neurology and psychiatry at his alma mater at one time professor of neurology at the College of the New York Ophthalmic Hospital for many years attending neurologist and psychiatrist at the Flower and Fifth Avenue hospitals, consulting neurologist and psychiatrist at the Metropolitan Hospital, consulting psychiatrist at the Middletown (N Y) State Homeopathic Hospital and consulting neurologist at the Pitkin Memorial Hospital Neptune N J, aged 71, died July 20 in South Norwalk, Conn. of heart disease.

Rudolph Jacoby * Boston Boston University School of Medicine, 1911 professor of dermatology and syphilology at his alma mater specialist certified by the American Board of Dermatology and Syphilology member of the American Academy of Dermatology and Syphilology, past president of the New England Dermatological Society, chief of the department of dermatology and syphilis Massachusetts Memorial Hospitals, consulting dermatologist Westboro (Mass.) State Hospital, Leonard Morse Hospital Natick, Mass. and the Anna Jacques Hospital, Newburyport, Mass., aged 52, died August 20.

Harry Gaylord Willard * Tacoma Wash. Rush Medical College, Chicago, 1904, past president of the Washington State Medical Association and the Pierce County Medical Society, president of the North Pacific Surgical Association member of the American Association for the Surgery of Trauma, fellow of the American College of Surgeons, served as a major in the medical corps of the U S Army during World War I, member of the staffs of St Joseph's and Tacoma General hospitals, district surgeon Chicago, Milwaukee, St Paul and Pacific Railway, aged 67, died, August 28.

John Luverne Hemstead * Albany, N Y, Albany Medical College, 1916 assistant in medicine from 1917 to 1919 associate from 1929 to 1932, clinical professor from 1932 to 1937 and since then associate professor of medicine at his alma mater specialist certified by the American Board of Internal Medicine, served as a first lieutenant in the medical corps of the U S Army during World War I and as an instructor at the Army Medical School, aged 49, for many years on the staffs of the Memorial Hospital and the Albany Hospital, where he died, August 22.

Henry Wilberforce Aikins, Toronto Ont., Canada, University of Toronto Faculty of Medicine, 1881, Victoria University Medical Department, Coburg, Ont., 1881, for many years registrar of the College of Physicians and Surgeons of Ontario, at one time associate professor of anatomy at the University of Toronto Faculty of Medicine, formerly senator and member of the board of regents of Victoria University, for many years a medical director of the Continental Life Insurance Company, aged 85, died, July 29.

Emil Altman, New York, College of Physicians and Surgeons, New York 1895, member of the Medical Society of the State of New York and of the American Psychiatric Association,

for many years chief examiner of the medical division of the city board of education, served during World War I and at the time of his death was a colonel in the medical reserve corps of the U S Army, aged 69, consulting neuropsychiatrist at the Beth Israel Hospital, where he died, September 11.

Herman Clay Frauenthal, New York, Bellevue Hospital Medical College New York 1897, member of the Medical Society of the State of New York, taught traumatic surgery and orthopedics to officers in the medical corps of the U S Army during World War I, aged 75, a founder, consultant in orthopedics and for many years chairman of the medical advisory board of the Hospital for Joint Diseases, where he died August 23 of carcinoma of the rectum.

Francis Bacon Camp * Springfield Mo., Emory University School of Medicine Atlanta, Ga., 1922 specialist certified by the American Board of Internal Medicine, fellow of the American College of Physicians, aged 45 on the associate staff of the Burge Hospital and the Springfield Baptist Hospital one of the founders of the library and on the active staff of St John's Hospital where he died August 11.

John Joseph White, New York University and Bellevue Hospital Medical College New York 1899 medical officer in the city fire department since 1907 an organizer and for many years treasurer of the International Association of Police and Fire Surgeons and Medical Directors of Civil Service Commissions, aged 66, died July 23 in the New York Post Graduate Medical School and Hospital following an operation for carcinoma of the stomach.

Charles Eckert Rowe Syracuse N Y Syracuse University College of Medicine 1916 member of the Medical Society of the State of New York and of the American Psychiatric Association medical superintendent of the Syracuse State Hospital formerly on the medical staffs of the Hudson River State Hospital Poughkeepsie and the Binghamton (N Y) State Hospital, aged 53, died July 30 of coronary occlusion.

Sherman Sedgwick Hesselgrave, Center City, Minn., University of Minnesota College of Medicine and Surgery Minneapolis 1894 served as a lieutenant in the medical corps of the U S Army during World War I lieutenant colonel U S Army reserve corps, aged 70, died August 12 in the Midway Hospital St Paul of ruptured abdominal aorta.

Harvey Willis Crook, Bishop Calif. California Eclectic Medical College Los Angeles 1914 member of the California Medical Association, past president of the Inyo Mono Counties Medical Society, for many years city and county health officer examining physician for the county Selective Service System, aged 69, died August 2 of heart disease.

Le Roy Happer Cheesman Mount Lebanon Pa. Western Pennsylvania Medical College Pittsburgh 1905 member of the Medical Society of the State of Pennsylvania, veteran of the Spanish-American War, commissioned a captain in the medical corps of the U S Army in 1919, for many years on the staff of the Pittsburgh Dispensary and the Prisoner Hospital Pittsburgh, aged 66, died August 15.

Raymond Arthur Ramsey * Columbus, Ohio Western Reserve University Medical Department Cleveland 1912, aged 55 on the staffs of the Children's Hospital University Hospital Mount Carmel Hospital St Francis Hospital and the Grant Hospital where he died August 19, of prostatic hypertrophy and postoperative hemorrhage.

Samuel W Hopkins * Walnut Ill. University of Pennsylvania Department of Medicine Philadelphia 1895, an Affiliate Fellow of the American Medical Association, past president of the Bureau County Medical Society, at one time president of the village board, aged 75, died, August 11, of coronary occlusion.

John Daniel Matz, Allentown, Pa. Medico-Chirurgical College of Philadelphia 1907 member of the Medical Society of the State of Pennsylvania served as a captain in the medical corps of the U S Army during World War I, on the staff of the Allentown Hospital, aged 72, died, August 13, of coronary occlusion.

Robert Ernest Gilbert Winter Haven Fla., Atlanta (Ga.) Medical College 1914 member of the Florida Medical Association, past president of the Polk County Medical Society, served during World War I, aged 51, died August 6 in Meridian Miss., of cerebral hemorrhage and chronic myocarditis.

Alva Andrew Young, Hammond Ind. Central College of Physicians and Surgeons, Indianapolis, 1905, served as a lieutenant in the medical corps of the U S Army during World

War I, aged 60, died August 9, in the Veterans Administration Facility, Hines, Ill., of hypertension and coronary sclerosis

Benjamin Comer Routon ♂ Ashdown, Ark. University of Arkansas School of Medicine, Little Rock, 1938, associate on the staff of the Texarkana (Texas) Hospital and the Michael Meglier Memorial Hospital, Texarkana, aged 29, died July 19, of cardiovascular accident due to an injury

Lee Jackson Wall, Fasley, S. C., University of Nashville (Tenn.) Medical Department, 1891, Vanderbilt University School of Medicine Nashville, 1891, member of the South Carolina Medical Association aged 84, died, August 6, of chronic myocarditis, chronic nephritis and arteriosclerosis

James Clyde Overall ♂ Murfreesboro, Tenn., Chattanooga (Tenn.) Medical College 1907, member of the Radiological Society of North America Inc., on the staffs of the Rutherford Hospital and of the Veterans Administration Facility aged 60, died, August 9, of coronary occlusion

Warren Hastings Smith, Newton N. J. Hahnemann Medical College and Hospital of Philadelphia, 1899, member of the Medical Society of New Jersey served as a member of the board of education aged 68, died, August 10, in Rochester N. Y., of cerebral hemorrhage due to a fall

William Sidney Bowers, Los Angeles College of Physicians and Surgeons, Los Angeles 1919, member of the California Medical Association on the staff of the Children's Hospital, aged 47, died September 4 in the Good Samaritan Hospital of chronic cardiorenal disease

Joseph Edward Preucel, Colfax, Wash., Rush Medical College Chicago 1895, member of the Washington State Medical Association served in the medical corps during World War I on the staff of St. Ignace Hospital, aged 74, died, July 13, of carcinoma of the prostate

John D. McGregor, Chicago, Rush Medical College, Chicago, 1891, member of the Illinois State Medical Society, at one time city physician, for many years president of the staff of the Sisters of St. Anthony de Padua Hospital, aged 72, died, August 5 of acute peritonitis

Jerrard Willard Coombs ♂ Camden, Ohio, St. Louis College of Physicians and Surgeons, 1896, Medico Chirurgical College of Philadelphia 1906 for many years served as a member of the board of education, aged 70, died, August 6, of carcinoma of the liver

George F. Hamel ♂ Kansas City, Mo. Berumont Hospital Medical College, St. Louis, 1888, also a pharmacist, for many years division surgeon for the Missouri Pacific Railway, on the staff of the St. Mary's Hospital, aged 82, died, July 3, of cerebral hemorrhage

Leonard Forrest Woodworth ♂ Le Center, Minn., State University of Iowa College of Medicine, Iowa City, 1908, for many years served as health officer, on the staff of the St. Peter (Minn.) Community Hospital, aged 62, died recently of coronary thrombosis

Joseph U. Vaillancourt, Quebec Que. Canada, Laval University Faculty of Medicine, Quebec 1906, professor of otorhinolaryngology at his alma mater, member of the Royal College of Physicians and Surgeons of Canada, aged 60, died suddenly recently

William Almon Wood ♂ Oakland, Calif., University of Southern California College of Medicine, Los Angeles 1906, on the staffs of the Childrens, Peralta, Providence and the Alameda County hospitals, aged 66, died, July 21, of coronary occlusion

William Gillespie Dana, Milwaukee, Wisconsin College of Physicians and Surgeons, Milwaukee, 1908, served in the medical corps of the U. S. Army during World War I, aged 68, died, August 1, of arteriosclerosis and diabetes mellitus

James Thomas McGoveron, Rochester, N. Y., Baltimore Medical College, 1898, for more than forty years associated with the city department of health, on the staff of St. Mary's Hospital, aged 70, died, August 16, of coronary occlusion

Edgar Ellsworth Kilby, Mackinaw, Ill., College of Physicians and Surgeons Keokuk, Iowa, 1896 formerly a member of the high school board, aged 71, died, August 17, in St. Francis Hospital, Peoria, of cerebral hemorrhage

David Jackson Hawk, Tower City, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1912, member of the Medical Society of the State of Pennsylvania, aged 55, died August 15, of coronary thrombosis

Coley C. Bowden, Troy, Ala. Memphis (Tenn.) Hospital Medical College, 1913 member of the Medical Association of the State of Alabama, aged 56, died August 15, in the Edge Hospital of carcinoma of the stomach

Douglas Thomas Ormond ♂ Waconia, Minn., St. Louis University School of Medicine, 1927, on the staff of St. Mary's Hospital, Minneapolis, aged 39, died, August 13, in the Abbott Hospital, Minneapolis, of septicemia

Charles L. Dillon, Boone Mill, Va., University College of Medicine, Richmond 1899, aged 73, died, July 22, in the Lewis Gale Hospital, Roanoke, of coronary thrombosis and bilateral bronchopneumonia

John Wesley Sutton, Petersburg Tenn. University of Tennessee Medical Department, Nashville, 1892, member of the Tennessee State Medical Association, aged 80, died, July 16, of cerebral hemorrhage

Charles Galitzan Marsters, Bass River N. S. Canada, Dalhousie University Faculty of Medicine, Halifax, 1920, served overseas with the Canadian Forces during World War I, aged 50, died recently

Frank Paine Witter, Tacoma Wash., University of Michigan Department of Medicine and Surgery Ann Arbor, 1887, at one time mayor of Rockford, aged 81, died recently of chronic myocarditis

John William Darlington, Valley Falls, Kan., College of Physicians and Surgeons, Baltimore 1887, member of the Kansas Medical Society, aged 88, died, August 21, of carcinoma of the rectum

John Adam Steurer ♂ Mount Vernon, N. Y. Bellevue Hospital Medical College, New York 1873, aged 90, died, August 5, of rupture of an abdominal aneurysm and arteriosclerosis

Ernest John Pieper Jr., Philadelphia Harvard Medical School, Boston, 1941, aged 25 intern at the Philadelphia General Hospital, where he died, August 3 of a streptococcal infection

Arthur J. Kleiser, Waveland, Ind., College of Physicians and Surgeons, Baltimore, 1885, president of the library board for many years, aged 80, died, August 20, of cerebral hemorrhage

Robert Rutledge Davisson, Winterset Iowa Rush Medical College Chicago 1890, member of the Iowa State Medical Society, aged 76, died, July 28, of carcinoma of the rectum

Barnett Herman Cooper, Glen Lyon Pa. College of Physicians and Surgeons Baltimore 1911 served during World War I, aged 54, died, August 8, of rheumatic heart disease

Frank E. White, Schenectady N. Y., Albany Medical College, 1904 member of the Medical Society of the State of New York aged 62, died July 22, of cerebral thrombosis

Uriah Alexander Cooke, Sylva, Ohio, Toledo Medical College, 1897, bank president, aged 72, died August 8, in St. Vincent's Hospital, Toledo, of coronary occlusion

Ralph Frederick Bacon, New Rochelle, N. Y. Milwaukee Medical College, 1902, aged 66 died, August 29 in the New Rochelle (N. Y.) Hospital of coronary thrombosis

R. Ora Hoffman, San Diego, Calif. Eclectic Medical Institute, Cincinnati 1891, member of the California Medical Association, aged 74, died, August 16, of heart disease

Vilas George Van Ornam ♂ Syracuse N. Y., George Washington University School of Medicine, Washington D. C., 1914, aged 52, died, July 4, of coronary occlusion

Howard Charles Crum ♂ Santa Cruz Calif., Chicago College of Medicine and Surgery, 1910, aged 58, died, July 29, of coronary occlusion and diabetes mellitus

Thomas Hugh Baife, Toronto, Ont., Canada University of Toronto Faculty of Medicine, 1923, aged 42, died of heart disease, August 16, while in swimming

Lewis Clinton Littlejohn, Oconee, Ill., Medical College of Ohio, Cincinnati, 1885, aged 86, died, August 27, in De Kalb of chronic myocarditis and prostatism

Orrin Aquilla Hess, Portland, Ore., Ohio Medical University, Columbus, 1906, for many years county physician, aged 66, died, August 11, of heart disease

Samuel Kahn, New York, Columbia University College of Physicians and Surgeons, New York, 1900, aged 63, died, July 13, of coronary thrombosis

Walter Stanley Bardwell, Newport, Wash., Northwestern University Medical School, Chicago 1907, aged 63, died July 4, of cerebral hemorrhage

Carl Felix Aussendorff ♂ Milwaukee, Universitat Leipzig Medizinische Fakultät, Saxony, Germany, 1910, aged 56, died, July 30 of coronary sclerosis

William Morse Eames, Northampton, Mass., Dartmouth Medical School, Hanover, N. H., 1897, aged 78, died, July 23 of valvular heart disease

Otto George Smersh, Omaha, University of Nebraska College of Medicine, Omaha, 1903, aged 62, died, July 8, of carcinoma of the prostate

John Crede Miller & Anderson, Ind., Indiana University School of Medicine, Indianapolis, 1930, aged 38, died, July 24, of coronary occlusion

Florence L. Barnes, Hinsdale Ill. Hering Medical College, Chicago, 1903, aged 83, died, July 27, in Minneapolis of coronary thrombosis

Adam Isaiah Berninger, Bradenton Fla. Physio Medical College of Indiana Indianapolis, 1895, aged 76, died, July 22, of acute myocarditis

John Quincy Adams West, Knoxville Tenn., Tennessee Medical College Knoxville, 1896, aged 72, died, July 2 of chronic pancreatitis

Karl Heinrich A. Hilger, Milwaukee, Milwaukee Medical College 1904, aged 80, died, July 24 of cerebral hemorrhage and arteriosclerosis

Julian Davis Miller, Mount Vernon Ky., University of Tennessee College of Medicine, Memphis, 1928, aged 40, died, July 23, of uremia

Joseph Henry Desmarais, Bristol Conn., Victoria University Medical Department, Coburg, Ont. Canada 1889, aged 77, died, June 15

John William Gorman, Brockton, Mass. College of Physicians and Surgeons, Boston, 1900, aged 64, died July 28 of bronchopneumonia

Charles S. Woodruff, Baltimore, University of Maryland School of Medicine, Baltimore, 1891, aged 73, died recently of chronic nephritis

William E. Oliver, Cairo, Ga. University of Georgia Medical Department, Augusta, 1902, aged 61, died recently of heart disease

Oliver C. Davis, Joliet Ill. Chicago Homeopathic Medical College 1882, aged 85, died, August 22, in the Silver Cross Hospital

Charles Lyman K. Hawley, Danville Ill. Chicago Homeopathic Medical College 1884, aged 80, died August 2 of heart disease

Joel M. Hubert, Cleveland, Texas Memphis (Tenn.) Hospital Medical College 1904, aged 67, died June 24 of angina pectoris

Albert S. J. Ragsdale, Russellville Ark., University of Louisville (Ky.) Medical Department, 1890, aged 74, died, July 14

Ethan Leo Connolly, Collingwood, Ont. Canada, University of Toronto Faculty of Medicine, 1900, aged 66, died, recently

Andrew Joe Lassiter, Adairville Ky., Vanderbilt University School of Medicine, Nashville Tenn., 1883, aged 84, died recently

John William de Courey King, Peterborough Ont., Canada Trinity Medical College, Toronto, 1899, aged 68, died, July 10

Thomas Thompson McRae, Brussels, Ont., Canada, University of Toronto Faculty of Medicine, 1905, aged 60, died, July 13

Fred George Morrow, Hamilton, Ont. Canada, Western University Faculty of Medicine, London, 1902, aged 61, died, July 9

William Charles Carroll, Davenport, Iowa College of Physicians and Surgeons, Keokuk, 1882, aged 86, died, July 15

Adolph William Faulbaum, Chicago, Washington University School of Medicine, St. Louis, 1903, aged 68, died, July 12

Edward Stanhope Smythe, Houston, Texas, Jefferson Medical College of Philadelphia, 1890, aged 74, died, August 15

Anthony H. Nanka, Gleason, Wis., Medizinische Fakultät der Universität Wien, Austria, 1888, aged 79, died, July 11

Cornelius H. Brantley, Bailey N. C. College of Physicians and Surgeons, Baltimore, 1887, aged 82, died, July 31

Robert Bird Wyatt, Fort Smith Ark., University Medical College of Kansas City, Mo., 1910, aged 78, died, June 1

Frank Marion Miller, Plainview, Ark., Kansas City (Mo.) College of Medicine and Surgery, 1919, aged 62, died recently

Eddie C. McCall, Savannah Ga., University of Georgia Medical Department, Augusta, 1888, aged 79, died, July 21

James Arthur Shacklett, Ethel, Mo., College of Physicians and Surgeons, Keokuk, Iowa, 1898, aged 66, died recently

James Woollsey Clark & Pittsburgh, University of Pittsburgh School of Medicine, 1908, aged 60, died, July 1

William Arthur Seanlon, Edmonton Alta. Canada, Trinity Medical College, Toronto, Ont., 1904, aged 60, died, June 27

Edwin E. Armstrong, Sylvania, Ohio, Toledo Medical College, 1897, aged 70, died, July 26, of coronary occlusion

Charles Adolph Frank, Albuquerque, N. M., Missouri Medical College, St. Louis, 1886, aged 84, died, August 16

Benjamin E. Harrison, Cottageville, W. Va., Starling Medical College, Columbus, 1878, aged 86, died, June 26

Frederick Stanley Whitaker, Kingston, N. C. Maryland Medical College, Baltimore 1913, aged 59, died, July 24

William Henry La Ferte, Canton, Ohio, Michigan College of Medicine, Detroit, 1885, aged 81, died, June 16

David H. Harris, Marion Ill. Missouri Medical College St. Louis 1897, aged 73, died, July 27, of heart disease

Francis Marion Payne & Chicago Hospital College of Medicine Louisville Ky., 1904, aged 75, died July 27

Walter E. Hendricks, Martinsville Ind. Medical College of Ohio, Cincinnati 1878, aged 89, died, August 21

James Henry Winter, Parkville Mo. Chicago Homeopathic Medical College, 1896, aged 71, died, July 28

Gideon Harmer Patton, Philadelphia Jefferson Medical College of Philadelphia 1902, aged 70, died July 26

Willis W. Hobson, Harrods Creek, Ky. Hospital College of Medicine Louisville 1885, aged 82, died, July 7

George W. Middleton Monrovia Calif., Medical College of Indiana, Indianapolis 1902, aged 69, died July 28

William C. Deixel, Portland Maine Maryland Medical College, Baltimore 1911, aged 56, died August 8

John W. Clark, Bellefonte Pa. Medico-Chirurgical College of Philadelphia, 1895, aged 74, died July 19

Roland Noah Smith, Augusta, Ark. Kentucky School of Medicine Louisville, 1893, aged 76, died June 8

Homer D. Williamson, Bethany Ohio, Starling Medical College Columbus, 1904, aged 63, died, June 16

John C. Hathaway Mechanicsburg Ohio, Starling Medical College Columbus 1898, aged 66, died, July 19

William R. Blankenship Seattle Missouri Medical College St. Louis 1883, aged 81, died July 24

J. C. Bushyhead, Chremore Okla. Missouri Medical College St. Louis 1891, aged 72, died, July 11

Chester Lee Hill, Yale Okla., Chattanooga (Tenn.) Medical College, 1900, aged 68, died recently

Francis Downing & Norwich Conn., Baltimore Medical College, 1908, aged 60, died August 10

DIED WHILE IN MILITARY SERVICE

Herman Irving Wortis & New York, Cornell University Medical College, New York 1933, lieutenant (junior grade) M. C. U. S. Naval Reserve, specialist certified by the American Board of Psychiatry and Neurology, Inc., assistant clinical professor of psychiatry at the New York University College of Medicine, member of the American Neurological Association, the American Psychiatric Association and the Association for Research in Nervous and Mental Disease, assistant neurologist at the Neurological Institute and Vanderbilt Clinic, aged 32, was killed in a navy airplane accident near Dahlgren, Va., August 23

Frederick Joseph Jardon, San Francisco, Creighton University School of Medicine, Omaha 1939, was commissioned a lieutenant (junior grade) MC-V (S), U. S. Naval Reserve on April 4, 1941, was called to duty at the Naval Training Station Norfolk, Va., June 9, 1941, since February 24 was stationed at the Norfolk Naval Hospital, at one time clinical assistant of psychiatry at the Woman's Medical College of Pennsylvania Philadelphia, aged 28, was killed in a navy airplane accident near Dahlgren, Va., August 23

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Cosmetics

The following items are abstracts of stipulations in which promoters of cosmetics have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Aknsol—Advertising in representations for this product which Colloidal Pharmaceuticals Inc. New York stipulated with the Federal Trade Commission in December 1941 to discontinue included the following: that a preparation of this kind helps a blenished skin or is a first aid for that condition *that it has no value in treating such blemishes as moles, warts, freckles, birthmarks or epitheliomas*; that the use of this lotion will prevent or overcome skin eruptions due to systemic factors incident to the age of puberty or adolescence; that it would be of any benefit in clearing up or eradicating large skin pores or toning up the skin or have any remedial actions beyond those properly attributable to a colloidal sulfur lotion.

Ar Jay Liquid Color Rinse—This is a color hair dye put out by the Ar Jay Laboratories Inc. Ontario Calif. Because the Federal Trade Commission found that the advertising did not reveal the important fact that the product may be dangerous to certain individuals the Ar Jay concern signed a stipulation with the Commission in May 1942 to discontinue its advertisements which did not conspicuously state: *Caution. This product contains ingredients which may cause skin irritation on certain individuals and a preliminary test according to accompanying directions should first be made. The product must not be used for dyeing the eyelashes or eyebrows to do so may cause blindness. The stipulation provided however that it would be sufficient for the advertisement simply to warn. Caution. Use only as directed on the label. If and when the label should bear the first-described caution and the accompanying labeling should give adequate directions for preliminary testing before each application of the dye.*

Beauty House Cosmetics—These are put out by an Albert H. Bach and a Pincus Bach trading as The Beauty House New York. In April 1942 these persons signed a stipulation with the Federal Trade Commission in which they agreed to discontinue misrepresentations about the prices and values of their products as compared to competitive ones and also to discontinue referring to their blend of face powder as *Holly wood* or otherwise using geographic or cosmetic names signifying an origin process or formula which the preparation designated does not in fact possess.

Coffelt's Never Fading Hair Coloring—That this nourishes or rejuvenates the hair and restores the original or natural color to the hair were claims which the Coffelt Chemical Company Inc. New York agreed to eliminate from their advertising in a stipulation which they signed with the Federal Trade Commission in June 1942. Further they agreed to discontinue any advertisements which failed to reveal that the product contains a metallic salt and should be used with care and only when the scalp is free from abrasions, sores, cuts or infections. The stipulation permitted however that when this warning is given on the label it will be sufficient for the advertisements to state: *Caution. Use only as directed. Tests made by the American Medical Association's chemists in 1929 when the product was known as Coffelt's Hair Coloring indicated that it then contained lead compounds and sulfur.*

Conti Complexion Cream—This is sold by Conti Products Corporation Brooklyn which in February 1942 stipulated with the Federal Trade Commission that it would discontinue the following misrepresentations: that the cream is effective in preventing or correcting skin dryness in helping maintain the proper moisture balance of the skin or in conditioning facial muscles or that it will have a beneficial effect on so-called worry lines. Also to be discontinued was the use of the word *tissue* in describing the preparation and representing that it builds up, nourishes or otherwise beneficially affects the tissue of the skin.

Hillshire Down Cosmetics—Under this designation one Marion E. Baldwin trading as Hillshire Down Killingly Conn. puts out a Goat Milk Hand and Arm Cream, a Goat Milk Massage and Cleansing Cream and a Lotion. In January 1942 this person signed a stipulation with the Federal Trade Commission agreeing to discontinue the following advertising misrepresentations: that these cosmetics will enable the body to breathe through the skin, have any effect in purifying the blood or reach deeply into the pores and bring out impurities; that any of them is a tonic for the skin or nerves or will tighten the facial muscles; feed the skin, nourish the skin tissue, help produce a healthy skin, be nonallergic to all persons or produce complete clear or new skin tissue. Further the promoter agreed to withdraw the claim that the nutritional value of 3 quarts of goat's milk is equivalent to that of 8 quarts of ordinary milk and to cease employing the word *tissue*.

or its abbreviation as part of a brand name designating any of these products or in any manner representing that any of them will affect the skin otherwise than by cleansing the surface of the outer skin tissues. According to the stipulation Marion E. Baldwin formerly sold the cosmetic designated *Hillshire Down Goat Milk Tissue* and *Foundation Cream* which is now put out as *Hillshire Down Goat Milk Night and Foundation Cream*.

Honey Facial Bath—The Federal Trade Commission found certain misrepresentations in the advertising of this product such as that it will cure or banish oiliness of the skin, enlarged pores, wrinkles, surface pimples or blackheads; that it is an astringent or will tone or bleach the skin; that superficial application of this product furnishes the skin with vitamins and that because of its honey content it possesses therapeutic value in excess of its action as a detergent or emollient. In May 1942 Elizabeth Redden of New York who puts out this preparation stipulated with the Federal Trade Commission that she would discontinue the foregoing misrepresentations.

Jordeau Waterless Shampoo—That this was actually waterless as the name implied was a competent treatment for dandruff and a preventive of colds or would actually eliminate dandruff were misrepresentations which Jean Jordeau Inc. South Orange N. J. agreed to discontinue in the advertising according to a stipulation that the concern signed with the Federal Trade Commission in May 1942.

Lanzette—This is a pumice stone device for removing superfluous hair and is marketed by an Edward A. Hochbrum trading as Lanzette Annette Lanzette and Lanzette Laboratories Chicago. In a stipulation that Hochbrum signed with the Federal Trade Commission in January 1942 he agreed to cease representing through use of the word *rid gone*, *disappeared*, *overcome* or similar expressions that the product will stop the growth of superfluous hair or that use of the device will have a beneficial effect on the skin or its appearance in excess of a transient glow or ruddiness.

Madame Hector's Pomado—This is put out by one Etta Hector trading as Madame Hector Products Company Brooklyn. In June 1942 she stipulated with the Federal Trade Commission that she would cease representing that her cosmetic product will increase the growth of hair, prevent loss of hair or correct the cause of falling hair. According to the stipulation her product will not accomplish these results.

Mahdeen—That this is a competent treatment or an effective remedy for itching scalp or falling hair that millions of users have found it to produce perfect scalp health and revitalize hair health or that it can eradicate dandruff or accomplish more than removal of the exfoliated scales of dandruff or is a remedy for eczematous scalp trouble or any similar affliction were advertising misrepresentations which the Mahdeen Company Macogoches Texas agreed to eliminate from the advertising in a stipulation which they signed with the Federal Trade Commission in June 1942.

Pompeian Milk Massage Cream—In June 1942 the Pompeian Company Inc. and the Joseph Katz Company advertising agency both of Baltimore stipulated with the Federal Trade Commission that they would discontinue these misrepresentations in the advertising: that the cream in question will remove dirt to a greater extent than ordinary cleansing methods or do more than remove pore deep dirt that when used for blackheads or whiteheads it will do more than facilitate the mechanical removal of such blemishes; that the use of this cream will leave the face looking years younger or that it contains pure milk or is capable of nourishing the skin. This stipulation supersedes one which the Commission accepted from the Pompeian concern in February 1941 and the terms of which were noted in this department of THE JOURNAL Nov. 8 1941 page 1643.

Superglo Henna Rinse and Lux Hair Dye (or Lux Hair Coloring)—In July 1942 Samuel Abrams trading as Luxe Manufacturing Company Brooklyn signed a stipulation regarding these products with the Federal Trade Commission. According to this he will no longer represent that *'Superglo Henna Rinse'* is not a dye or that it imparts a natural shade to the hair. He further stipulated that in the sale of *Lux Hair Dye* also known as *Lux Hair Coloring* he would discontinue any advertisements which did not contain the following warning: *Caution. This product contains ingredients which may cause skin irritation to certain individuals and a preliminary test according to accompanying directions should first be made. This product must not be used for dyeing the eyelashes or eyebrows to do so may cause blindness. The stipulation permitted however that the warning in the advertising might be limited to the statement: Caution. Use only as directed on label. If and when the label bears the first-described warning conspicuously displayed and the accompanying literature contains adequate directions for such preliminary testing before each application.*

Tuch Up—Nu Tone Products Corporation New York which puts out hair dye preparations under this name stipulated with the Federal Trade Commission in August 1941 that it would discontinue the following misrepresentations: that these products will cause the hair to look natural or have a soft texture or that they will have any beneficial effect on such texture that their use will banish gray hair or cause one to remain young; that they are vegetable compounds and will cover hair roots or have any effect on the color of hair roots; that hundreds of thousands or any other number of women have specified their requirements for a hair dye or that the Tuch Up dyes are new or made of ingredients of recent origin or development. The Nu Tone concern further agreed to cease representing that it manufactures or controls the manufacture of the dyes that it sells unless and until such is the fact.

Correspondence

"TOTAL COLLAPSE ASSOCIATED WITH PHYSICAL EXERTION"

To the Editor —In the August 22 issue of THE JOURNAL, on page 1431, is an editorial comment entitled "Total Collapse Associated with Physical Exertion." I must take issue with the authors quoted who conclude that severe physical exertion or trauma can produce coronary occlusion.

Reviewing the recent report of Jokl and Suszman (Mechanisms Involved in Acute Fatal Nontraumatic Collapse Associated with Physical Exertion *Am Heart J* 22 761 [June] 1942) you write that these authors, analyzing 66 cases of sudden death in which clinical data and complete necropsy reports were available, came to the not unexpected conclusion that collapse following exertion is almost invariably due to circulatory disease of long standing. You say that the authors found that acute coronary occlusion was the second in order of frequency of the "circulatory disease of long duration" found at necropsy. Actually, however, in this particular article no "clinical data and complete necropsy reports" are available. Autopsy reports are not cited but rather are promised in a future publication in press. Yet the authors do not hesitate to write in their summary that "the pathologic findings are given and interpreted." You have used the expression of the authors and unintentionally given the impression that these were available.

Under the caption "Chest Injury and Coronary Occlusion" two other authors are quoted. The first (Sigler, L. H. Trauma of the Heart Due to Nonpenetrating Chest Injuries, *THE JOURNAL* July 11 1942 p 855) presents presumably 5 such cases, but only in the fourth does he state that the infarction was undoubtedly due to coronary artery thrombosis which was precipitated by the injury. The story is that of a man aged 52 who tripped and fell unconscious and "an electrocardiogram taken later showed myocardial infarction." The legend below the electrocardiogram reads "About four weeks after accident." I cannot understand why a definite time is not stated, rather than "later" or "about four weeks." Surely the author knew the details. Why did he not present an electrocardiogram taken as soon as possible after the accident? With the paucity of data presented it is just as reasonable to assume that the man experienced a coronary occlusion first and that his fall resulted from it.

The last author quoted (Leinoff, H. D. Acute Coronary Thrombosis in Industry, *Arch Int Med* 70 33 [July] 1942) admits in his second paragraph that he should not have used the expression "acute coronary thrombosis," for he writes "The diagnosis, most often, was acute coronary thrombosis with myocardial infarction, but a better diagnostic term would have been acute traumatic heart disease with myocardial and pericardial damage." In his conclusions too he states "The clinical picture is that of an acute pathologic condition of the heart and closely resembles that of coronary occlusion, from which it is differentiated by the history." Then why mislead his readers? He too gives no evidence that trauma causes coronary thrombosis. In case 6 he states "The electrocardiographic diagnosis was auricular fibrillation, with a controlled ventricular rate, changes suggestive of myocardial damage and residual signs of anterior coronary occlusion."

Yet in the next paragraph, dealing with the postmortem examination, the last three sentences are "The ostia of the coronary arteries are patent. The coronary vessels are sclerotic and the lumens narrowed. There is no evidence of occlusion, however." Of the 18 cases reported this was the only 1 with a postmortem examination, and this case, on the author's own autopsy protocol, was not coronary occlusion or thrombosis.

I realize fully that severe exertion and trauma, direct or indirect to the chest or abdomen can produce nonfatal and fatal

injury to the heart and large blood vessels in the chest. I fully agree on this with Jokl and Suszman, Sigler and Leinoff, but I maintain that coronary occlusion does not result from these causes.

In the foreign literature the same few cases are repeatedly cited uncritically to show relationship between trauma and coronary occlusion. This is not the place to go into the matter in detail, but we have frequently presented data on the precipitating factors associated with coronary occlusion. My colleagues and I have definitely concluded that neither severe exertion nor trauma produces coronary occlusion (Master, A. M., Dack, Simon, and Jaffe, H. L. Factors and Events Associated with Onset of Coronary Artery Thrombosis, *THE JOURNAL*, Aug 21, 1937 p 546, Activities Associated with the Onset of Acute Coronary Artery Occlusion, *Am Heart J* 18 434 [Oct] 1939; Master, A. M. Angina Pectoris and Cardiac Infarction from Trauma, Correspondence, *THE JOURNAL*, July 29, 1939, p 440; Master, A. M., Dack, Simon, and Jaffe, H. L. The Relation of Effort and Trauma to Acute Coronary Occlusion, *Indust Med* 9 359 [July] 1940; The Role of Effort, Trauma, Work and Occupation in the Onset and Subsequent Course of Coronary Artery Occlusion, *M Inn District Columbia* 10 79 [March] 1941; Master, A. M. Effort, Trauma, Occupation and Compensation in Heart Disease, *Bull New York Acad Med* 17 778 [Oct] 1941). They can and do cause infarction without occlusion, heart failure and other serious cardiovascular conditions. It will be apparent that the chief reason for the difference of opinion as to whether severe exertion and trauma cause coronary occlusion (coronary thrombosis) or not lies in the fact that terms are used loosely. Leinoff is apparently beginning to appreciate this fact. We have emphasized the necessity of a correct nomenclature of coronary disease (Master, A. M., Dack, Simon and Jaffe, H. L. Nomenclature in Coronary Artery Disease, *Modern Concepts of Cardiovascular Disease* 10, No 11 [Nov] 1941). Severe exertion or trauma often produces myocardial contusion, infarction or necrosis without occlusion, i. e. acute coronary insufficiency, but this must not be confused with myocardial infarction resulting from coronary occlusion. The former, i. e. acute coronary insufficiency, is the result of prolonged ischemia of the heart muscle resulting in focal disseminated necrosis of the myocardium, subendocardial in location. The endocardium and pericardium are not involved. The electrocardiogram is characteristic: RS-T depressions and T wave inversions, without Q waves. Coronary occlusion (coronary thrombosis), on the other hand, is a complete closure of a coronary artery, with massive, confluent, through and through infarction as a rule. The endocardial involvement often results in mural thrombosis with embolization, and the pericardial involvement produces pericarditis. The electrocardiogram is characteristic and in the vast majority of instances pathognomonic, consisting of RS-T elevations progressing to deeply inverted T waves, large Q waves and a reciprocal relationship between leads 1 and 3. There are other important clinical distinctions. These have been presented voluminously in the German literature for years and in the American for the past few years, material which my colleagues and I recently partially reviewed (Master, A. M., Gubner, Richard, Dack, Simon, and Jaffe, H. L. Differentiation of Acute Coronary Insufficiency with Myocardial Infarction from Coronary Occlusion, *Arch Int Med* 67 647 [March] 1941).

My purpose in writing is thus twofold: in regard to whether severe exertion or trauma produces coronary occlusion, to show that the authors cited have given no proof for this, and, second, to make a plea that terms be used correctly in the nomenclature of heart disease, particularly with respect to coronary artery disease and myocardial infarction.

ARTHUR M. MASTER, M.D., Bethesda, Md

Alabama June Report

The Alabama State Board of Medical Examiners reports the written examination for medical licensure held at Montgomery, June 16-18, 1942. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Thirty-four candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Howard University College of Medicine	(1942)*		1
Emory University School of Medicine	(1941)		1
Rush Medical College	(1942 2)*		2
University of Louisville School of Medicine	(1942 2)*		2
Tulane University of Louisiana School of Medicine	(1941)		
(1942 10)*			11
Johns Hopkins University School of Medicine	(1942)*		1
Harvard Medical School	(1941) (1942 2)*		3
Washington University School of Medicine	(1942)*		1
Long Island College of Medicine	(1942 5)*		5
Duke University School of Medicine	(1938)		1
Jefferson Medical College of Philadelphia	(1942)*		1
University of Pennsylvania School of Medicine	(1942 4)*		4
Vanderbilt University School of Medicine	(1942)*		1

Twenty-two physicians were licensed to practice medicine by reciprocity and 2 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners from May 23 through July 30. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Arkansas School of Medicine	(1938)		Arkansas
Emory University School of Medicine	(1938) (1940 2)		Georgia
(1938) Louisiana

Colorado June Report

The Colorado State Board of Medical Examiners reports the written examination for medical licensure held at Denver, June 9-11 1942. The examination covered 8 subjects and included 58 questions. An average of 75 per cent was required to pass. Fifty-three candidates were examined, all of whom passed. Three physicians were licensed to practice medicine by endorsement. The following schools were represented:

School	PASSED	Year Grad	Number Passed

MEDICOLEGAL ABSTRACTS

Malpractice Jurisdiction of Industrial Commission, Release Given Employer by Injured Employee—On June 18, 1938, during the course of his employment as a welder, the plaintiff injured the little finger of his left hand, the injury consisting of a deep laceration nearly encircling the finger and exposing the tendons and a fracture of the proximal phalanx in four different places. He was immediately sent by his employer, at the request of its insurance carrier, to the office of the defendant physicians for treatment. One of the defendants treated the plaintiff for shock, rendered first aid, took four sutures in the laceration and bandaged the finger. About two weeks later a roentgenogram, taken for the first time, disclosed that the finger was fractured and that the comminuted fragments of bone were not completely in place, there having been some degree of telescoping or fixation of one fragment into the other. The defendants continued to treat the patient until July 11 but made no attempt to reduce the fracture merely cleansing and bandaging the laceration from time to time. The fracture subsequently healed with a reasonably good alignment, and the plaintiff returned to work, although he had permanently lost the power of extension of the finger. Contending in effect that the condition of his finger was the result of the defendants' failure to use the roentgen ray and to apply a splint to the fractured finger, the plaintiff filed suit against the physicians for malpractice. From a judgment of the trial court, sitting without a jury, in favor of the plaintiff, the defendants appealed to the district court of appeal, second district, division 2, California.

It was the duty of the defendants, said the court of appeal, to apply to the treatment of the plaintiff's finger that degree of care, skill, knowledge and attention ordinarily possessed and exercised by practitioners of the medical profession under similar circumstances in the locality in which the treatment was administered. Medical experts testified that in failing to take a roentgenogram of the plaintiff's finger when he first appeared for treatment the defendants did not employ the required degree of care and skill. Furthermore, one of the defendants admitted that the use of the roentgen ray is endorsed in discovering fractures of small bones such as the fracture of the plaintiff's little finger. It was also established by expert testimony that one who possessed the degree of care and skill ordinarily used by physicians and surgeons in good standing practicing in that locality would have employed extension to the plaintiff's finger by the use of splints in order to reduce the fracture and that the ordinary standard of care of physicians and surgeons practicing in the locality in question required that a splint be applied to a laceration of the type received by the plaintiff in order to protect the tendons and prevent any stress or strain on them. On the basis of all the evidence, the court of appeal concluded that the record contained sufficient evidence to support the finding by the trial court that the defendants were negligent in failing to discover and reduce the fracture and in addition, that they were negligent in failing to apply a splint to the plaintiff's finger in order to protect the tendons.

In December 1938 the plaintiff, for a valuable consideration executed a complete release to his employer for any and all claims which existed at that time, especially with reference to this particular injury, which release was approved by the industrial accident commission. The defendants contended, in effect, that since the plaintiff's original injury was compensable under the workmen's compensation act therefore the industrial accident commission had exclusive jurisdiction over the injury and a release to the employer was a bar to the present action against the physicians who acted on behalf of the employer and its insurance carrier. The court of appeal said that if, as contended by the defendants, the industrial accident commission had exclusive jurisdiction over claims for the recovery

of damages for malpractice of a physician in the treatment of an industrial injury, it might properly be held that the release was a bar. Such, however, is not the law. In cases in which recovery is sought by an employee against his employer or the employer's insurance carrier for a new or aggravated injury resulting from the negligence of a physician in treating an industrial injury, the industrial accident commission has exclusive jurisdiction to determine the claim. But when as in the instant case, recovery is sought against the physicians only, for the new or aggravated injury which resulted from the negligence of the physicians who treated the plaintiff's industrial injury, and neither the employer nor the latter's insurance carrier is a party, the plaintiff may recover in an ordinary civil action for malpractice. The court therefore concluded that the release was effective only as to the plaintiff's employer and the insurance carrier and did not bar his action against the defendants for the separate and subsequent injury which was caused by their malpractice. The judgment in favor of the plaintiff was therefore affirmed.—*Smith v. Coleman*, 116 P. (2d) 133 (Calif., 1941).

Pharmacists Liability for Selling Poison to Intoxicated Person—Mrs. Mosely sued the Bennett Drug Stores, Inc., for damages for negligence. She alleged that, while her husband was so intoxicated on a stated night that it was obvious to any person of ordinary intelligence that he was not in possession of his faculties, he purchased from the defendant some carbolic acid and immediately drank it dying within a few minutes. The defendant, she alleged, owed her husband a duty not to place a dangerous drug or poison into his hands while he was so obviously in a state of intoxication that he could not understand and comprehend the dangers of the poison and the defendant was negligent in selling the goods to him when he was so intoxicated she further alleged. The defendant interposed general and special demurrers, which the trial court overruled, and the defendant then brought exceptions to the court of appeals of Georgia, division No. 2.

The defendant denied liability contending that the proximate cause of the death of the plaintiff's husband was his voluntary drunkenness not its sale of the poison to him, citing *Meyer v. King*, 72 Miss. 1, 16 So. 245 and *King v. Hankin*, 80 Ala. 505, 60 Am. Rep. 119, both of which cases held that the proximate causes of the deaths in the cases involved were the voluntary drunkenness of the deceased persons and not the sale of a poison to them. It is the general rule, said the court of appeals, that the duty which one owes to avoid the consequence of another's negligence is that degree of ordinary care which would be exercised by a sober person. There are exceptions to the rule, however, and we think that the exception applies in this case. It is clear to us that a person who is too drunk to understand the dangerous nature of carbolic acid is one of the class designed to be protected by the provision in the pharmacy practice act which prohibits the sale of certain poisons, listed among which is carbolic acid, unless, among other things, on due inquiry it is found that the person to whom the poison shall be delivered is aware of its poisonous character and represents that it is to be used for a legitimate purpose (Mississippi Code, section 42-701). The exception to the rule we have mentioned is based on the doctrine of last clear chance, or humanitarian doctrine and is predicated on the theory that there is a duty owed to one who has been so negligent as to render himself incapable of exercising ordinary care to protect himself, after such incapacity is known. This doctrine has been applied in numerous cases in which a drunken or a disabled person was in a place of danger and in which his helplessness or facts indicating helplessness were known to another. When this situation exists it is such other person's duty to exercise ordinary care to avoid injuring the unfortunate person even though if it had not been for the previous negligence, such as voluntary drunkenness, he could have put himself in a place of safety by the exercise of ordinary care. In brief said the court, a person is charged with knowledge that a man staggering drunk is incapable of exercising ordinary care for his own safety, and he is bound to deal with him with that fact in mind.

The fallacy of the Mississippi and Alabama cases cited by the defendant as relieving it from liability lies in the fact that those cases absolved the defendants by projecting the voluntary drunkenness of the decedents above and beyond the negligence of the defendants, when as a matter of fact that negligence was at an end at the time of the defendants' negligence and this negligence of the decedents charged the defendants with knowledge that their acts might reasonably result in injury to the decedents or others. Of course no person is chargeable with unforeseeable consequences. However, it seems to us, said the court, that the conduct of a man who is staggering drunk is so unpredictable that one selling poison to him would be liable for whatever injury resulted. The defendant assumes that the decedent drank the poison with the intent to commit suicide. Even if this would relieve the defendant it does not appear from the petition filed by the plaintiff that the decedent drank the poison knowing that it was poison and with the intention of taking his life.

In the opinion of the court, the petition filed by the plaintiff set forth a cause of action and the action of the trial court overruling the demurrers was proper. The judgment of the trial court was accordingly affirmed.—*Burnett Drug Stores, Inc., v. Mosely* 20 S F (2d) 208 (Ga., 1942)

Dental Practice Acts Sale of Dentures by Dental Laboratories—In 2 cases the Supreme Courts of Illinois and Indiana passed on the right of persons operating dental laboratories for the making of dentures to engage in such business without being licensed to practice dentistry. The decision in each case depended on the particular statutory wording of the dental practice act in the respective state.

In Illinois the dental practice act provides in effect, that such persons have to possess a license to practice dentistry unless the impression from which the plate was made was taken by a licensed dentist, the placing and adjusting of the plates in the oral cavity was performed by a licensed dentist and the person operating the laboratory made no offer to sell the plates or the services rendered in their construction to the general public. The evidence showed that the latter condition was breached by the plaintiffs in that they advertised their business by offering to sell full or partial dentures to the public. The Supreme Court of Illinois upheld the constitutionality of the act and dismissed the plaintiffs' bill to restrain the attorney general and the Department of Registration and Education from prosecuting them criminally.

In Indiana, the dental practice act exempted from the licensing requirement the "performance of mechanical work on inanimate objects by any person employed in or operating a dental laboratory." The evidence showed that the defendant operated a dental laboratory in which artificial teeth were manufactured from impressions made by a licensed dentist, the finished product being sent directly to the customer who paid both the defendant and the dentist. Since the Indiana statute did not forbid a sale directly to the user, the Supreme Court denied the petition of the state board of dental examiners for an injunction to restrain the defendant from the alleged practice of dentistry without a license.—*Lasdon v. Hallahan, Director of Registration and Education* 36 N E (2d) 227 (Ill., 1941), *State ex rel Kennedy* 36 N E 276 (2d) (Ind., 1941)

Accident Insurance Death Following Administration of Spinal Anesthesia—A life insurance policy, written by the defendant company, provided for the payment of double indemnity in case death occurred "as a direct result of bodily injuries effected through external violent and accidental means, where there is a visible contusion or wound on the exterior part of the body. While this policy was in force the insured submitted to an operation for the treatment of chronic inflammation of the gallbladder. Prior to the operation a spinal anesthetic was administered. Shortly after its administration, and before the operation was begun, the patient complained of shortness of breath, and his respiration became graduated and shallow. Emergency measures immediately undertaken were in vain, the insured's respiratory system became completely paralyzed or anesthetized and he died. Subsequently his adminis-

trator sued the defendant insurance company to recover under the double indemnity provision of the policy and, from an adverse judgment in the trial court, appealed to the Supreme Court of North Carolina.

The injection of the spinal anesthesia was performed with the instruments, force and dosage customarily used and approved by the medical profession and the point at which the injection was made in the spinal column was the point ordinarily used for such injections. The Supreme Court first pointed out that the deceased's insurance was not against accidental death; it was against death resulting from accidental means. If the death resulted from the use of ordinary means voluntarily employed in a not unusual or unexpected way, it was not produced by accidental means. The court found that in addition to the usual and expected sedative effect of the anesthetic there occurred an unexpected result due to the collapse of the respiratory system. If it is conceded, the court pointed out, that there was an accidental death caused by external means—the injection of the anesthetic—the fact still remained that the means was not accidental but was voluntarily authorized and was intentional.

The plaintiff contended, however, that the evidence showed the head of the deceased was accidentally or unintentionally lowered after the anesthetic had begun to affect his respiratory system and that this lowering of the head tended further to increase the risk and caused the death. She contended that this evidence brought her case within the provisions of the policy. The Supreme Court could not agree with this contention and said that even if it was conceded that this evidence tended to show "death by accidental means," no visible contusion or wound on the exterior part of the body was caused thereby, for there was no causal connection between the wound made by the injection and such "death by accidental means." The wound was voluntarily made with the full consent of the patient. The Supreme Court therefore concluded that if the cause of the death was caused by the injection of the anesthetic, only an accidental death from an intentional act performed in the usual and ordinary way, with full consent, was established. The element of accidental means was absent. If on the other hand, it was related to the accidental lowering of the patient's head in the excitement caused by the sudden emergency which arose when his respiratory system became affected, there was no exterior visible wound or contusion caused thereby. Accordingly, the court held that the judgment of the trial court in favor of the defendant was correct and it was therefore affirmed.—*Fletcher v. Security Life & Trust Co.*, 16 S E (2d) 687 (N C, 1941)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Pertussis Antitoxin.—Weichsel and his colleagues examined the serums of patients with whooping cough, normal children and children who had been inoculated with pertussis vaccines for pertussis antitoxin. They determined whether pertussis antigen produced antibodies in the human being. Pertussis antitoxin was rarely present in serum from normal children. Likewise the serum of adults irrespective of a history of pertussis, and children thought to be immune had little antitoxin. During active whooping cough the serum of a certain percentage of children had a positive titer, but that of many children during convalescence from the disease failed to have any antitoxin. The injection of detoxified pertussis antigen raised the titer in a fair percentage of these children and of healthy children treated with large doses. The maximal antitoxin response was obtained from two to eight weeks after the injections were completed. There was little antitoxin in the serum of children who had received large doses of bacterial vaccine. The bacterial vaccine lacked the power to act as a primary stimulus to the subsequent injection of small doses of formaldehyde treated pertussis filtrate.

Fibrocystic Disease of Pancreas.—The general aspects of fibrocystic disease of the pancreas are reviewed by Daniel, who presents 8 cases of the disease. The symptoms are those of malnutrition and of chronic pulmonary disease with frequent large, fatty, foul stools. There is no proved etiology. In many instances it is apparently familial. Vitamin A deficiency has been suggested, and there is much evidence in favor of such a theory. Whether it is congenital is unproved. One of the author's patients had the disease, yet his twin of the same sex was free from similar symptoms. Although each patient presented evidence of pulmonary and pancreatic damage the respiratory symptoms (coughing) were usually more alarming. At necropsy the pathognomonic changes of the pancreas are seen chiefly in the microscopic sections rather than on gross observation. Microscopically, the exocrine parenchyma is extensively damaged, this is illustrated by fibrosis, distention of the ducts and acini with inspissated secretion, degenerative changes of the cells and acute and chronic inflammatory cell infiltrations. Squamous cell metaplasia is usually prominent in the lungs. Until recently the disease was not diagnosed during life. The three symptoms which should cause the disease to be suspected are failure to gain weight or malnutrition, respiratory distress and large, fatty, homogeneous, foul stools. The prognosis is poor but recent

methods of treatment offer some hope. One of the author's patients is alive at the age of 22 months, thirteen months after onset. Pancreatic products were the chief therapeutic agent. The amount to be given is empiric, but overtreatment is probably better than the reverse. From 0.3 to 5 Gm of the granules has been given with each feeding until a response was obtained. Large doses of vitamin A should be given. The diet should be low in fat content. With a fatty liver choline is of value.

Hemophilus Pertussis.—In intradermal tests with the purified agglutinin prepared from phase I organisms Flossdorf and McGinness observed no primary toxicity in either rabbits or approximately 650 human beings, including normal babies 8 to 14 months of age. In children vaccinated as long as six years ago in children who had recovered from the disease and in hyperimmunized adult donors an immune response of the immediate type was obtained to intradermal tests. Hemophilus pertussis is of a single serologic type. A related organism Bacillus parapertussis has been shown to cause some cases of whooping cough. H. pertussis in the laboratory exists in four variant forms as "phases" which are serologically distinct. Only organisms in phase I are of clinical significance. Two toxins occur in H. pertussis, one is thermolabile and the other is thermostable. These toxins alone apparently are not adequate for establishing immunity by their use as toxoidal immunizing agents unaided by reagents to produce antibacterial immunity. For such a purpose it is essential that organisms used in the preparation of vaccine be in phase I. On the basis of agglutination titer only little cross protection can be expected from the use of standard vaccine. Hyperimmune human serum of known high degree of effectiveness in prevention and treatment has been shown by agglutination to be high in its content of antibacterial antibody. The serum contains no demonstrable antitoxin. Cross protection might be expected but as yet no such clinical evidence exists. Clinically, purified agglutinin is giving promise of a useful test reagent for susceptibility to pertussis.

Prostatitis.—In 6 men whose major complaint was chronically recurrent pain in the lower right quadrant of the abdomen Freund, after a thorough examination, found that prostatitis existed in each. The inflammation was confirmed by the presence of definite pus in the expressed secretions of the gland. No other objective signs were present which could be considered as relevant to the chief complaint. The complaint had been present in all but 1 for from one to ten years. One patient was subjected to a hernioplasty and then to a hemorrhoidectomy, primarily for relief of the abdominal pain, but with no relief. In 3 the diagnosis of chronic appendicitis was considered and in 1 appendectomy was entertained. The etiologic factor of the prostatitis varied, being masturbation in 1, prostatic hypertrophy and infection in 1, a recurrent gonococcal urethritis in 1 and coitus interruptus in the remainder. Pressure over the tender portion of the prostate reproduced exactly the pain complained of by the patients. It is possible that the prostate is an offending agent in

abdominal pain may be occasionally overlooked, making for a better understanding of "Pain is not where you find it" Conservative local therapy directed toward the prostatitis resulted in relief of signs and symptoms in 4

Intrapericardial Teratoma and Tumor of Heart—Beck reports the first successful removal of an intrapericardial teratoma of the heart. The lesion was completely removed, and the patient has remained well for four years. From another patient he removed a tumor-like mass located in the wall of the left ventricle. The identity of the lesion has not been established, but it was probably not a true neoplasm. The patient has been well for eighteen months after operation. An aneurysm of the left ventricle has not developed. The grafting of a segment of pericardium or fascia lata on the ventricle to reinforce the weakened area and to prevent an aneurysm from forming is illustrated.

Lymphatic and Venous Spread of Carcinoma of Rectum—Of the four main routes by which carcinoma of the rectum may spread, Grinnell discusses two: the lymphatic and the blood stream. The other two routes are direct extension and transplantation through the peritoneal cavity. Seventy-five specimens of the rectum and rectosigmoid were cleared by the modified Spalteholz technic and studied for the two routes of metastasis. Lymphatic metastasis was found in 41, or 55 per cent of the specimens. Significant intramural lymphatic spread was not seen. The main extramural lymphatic spread was upward along the superior hemorrhoidal vessels. Only 4 of 17 patients with node metastasis, having tumors below the peritoneal reflection, could have had adequate node removal by perineal excision. There was only 1 proved case of lateral lymphatic spread along the middle hemorrhoidal vessels and only 1 of downward spread. Metastasis to the paracolic nodes was not found. The incidence of node metastasis was 18 per cent higher when the tumor was completely annular than when it was not. Evidence of blood vessel invasion was present in 36 per cent of 75 specimens and in 41 per cent of a combined group of 162 colon and rectal tumors. The incidence of such invasion was four times as great in grade 3 as in grade 1 tumors, being present in all the former. Twenty-seven, or 90 per cent, of the 30 cases with visceral metastasis showed blood vessel invasion. Failure to find local blood vessel invasion is strong evidence that no visceral metastasis exists.

Thrombotic Barrier and Varicose Veins—Gault describes a nonoperative method of limiting the chemical thrombophlebitis that follows retrograde injection of the internal saphenous vein during high ligation to its thigh portion. The internal saphenous vein at the level of the knee is palpated. The vein is injected with 1 cc of a sclerosing solution (sodium morrhuate). If no thrombosis occurs in three or four days the vein depending on the caliber of the vessel, is reinjected with 1.5 to 2 cc of the solution. Any palpable tributary in the region of the knee is similarly treated. Ligation and retrograde injection are performed when a firm thrombus has resulted. This usually takes ten to fourteen days. The occluding thrombus or thrombotic barrier prevents the sclerosing solution injected into the internal saphenous vein at operation from passing below the level of the knee. In 95 cases a thrombotic barrier preliminary to ligation was attempted, and in 62 a firm thrombosis of the saphenous vein at the knee was obtained after the first injection, in 14 two injections were necessary, in 12 three or four injections were required and in 7 no thrombosis was obtained after four injections, and ligation with retrograde injection was performed in the usual manner. The patients in whom a thrombotic barrier was produced were able to engage in their usual pursuits with no discomfort or disability. Possibly the absence of disabling symptoms may be explained by two factors: the limitation of the thrombophlebitic and periphlebitic process to a smaller surface and the absence of inflammation in the lower region of the knee and leg, resulting in painless locomotion.

Modified Fenestration Technic—Shambaugh modified the original fenestration technic, used it in 103 cases and states that the modification adds to the surgical treatment of otosclerosis, as with it he has obtained lasting and significant hearing improvement in about 75 per cent of cases as against 25 per cent with the original technic. The most important improvement of the modified fenestration seems to be the use of constant irrigation. Six months is the minimal postoperative period that must elapse before results are regarded as "final" and probably permanent. The osteogenesis and fibrosis causing closure of a fistula are most active during the first three months and in most cases tend to reach a state of equilibrium about six months after operation. In every revision failure was due to closure of the fistula by new bone or fibrous tissue. At least six, and preferably eight, months should elapse before a revision is attempted so as to permit active osteogenesis and fibrosis to reach a state of equilibrium. With revisions and bilateral operations in some instances a significant improvement in hearing (average 24.4 decibels) was secured in 87 of 103 cases in which operation was performed between July 1938 and September 1941. No dead labyrinths, serious complications or fatalities resulted in one hundred and ninety-four consecutive operations performed on 154 patients from July 15 1938 to April 24, 1942.

Status Asthmaticus—Bases and Kurtin state that 6 of the 7 patients who died of status asthmaticus at the Mount Sinai Hospital and on whom necropsy was performed in the past fifteen years died from blocking of the tracheobronchial airway by excessive outpouring of secretion. A review of similar cases from the literature, that is, only those in which death was due to status asthmaticus, reveals that in many death could have been averted by bronchoscopic removal of the obstructing secretion. The observations in the 7 cases and those reported in the literature are so striking that it is felt that bronchoscopic suction should be performed on all patients who, in spite of all therapy, continue to get worse. If increasing dyspnea, deepening cyanosis and progressive weakness lead to semistupor at least at this point, if not before, bronchoscopy should be performed. In 1 such case in which bronchoscopy was performed there was immediate improvement. During the next few days in an oxygen tent the patient continued to improve, though occasional asthmatic episodes still occurred. There was no recurrence of cyanosis or dyspnea. The bronchoscopic aspiration was life saving.

Treatment of Shock from Crush Injury—Duncan and Blalock tried to prevent the peripheral circulatory failure that follows crush injury in animals. Practically all such control animals died after an average survival of seven and fifty-five hundredths hours. In his experiment he hoped to prolong life so as to observe the animals during the period in which oliguria and uremia followed by death develops in clinical cases of crush syndrome. The injection of plasma to 15 animals prolonged the life of 6 sufficiently for observation and in spite of the similarity of the early essential features oliguria casts in the urine, uremia and death in several days was not observed in the experiments. Maintenance of the extremity at a low temperature during the time the mechanical press was in place exerted a definitely protective influence. This was probably due to the fact that metabolism of the tissues was reduced and that less injury resulted from the inadequate blood supply. Cooling of the part after the press was removed did little if any good, as most likely the mechanical injury and the anoxia had already exerted their deleterious effects. In several recent experiments the press was left on the extremity for fifteen rather than for five hours when more blood plasma was admin-

istered intravenously than was lost at the site of injury. These animals died within twenty-four hours after the press was removed, probably from absorption of toxic products from the injured and ischemic extremity. The prolonged anesthesia was probably an additional factor. Further studies are indicated.

Prothrombin Test—Abbott and Holden employed the prothrombin test on 120 patients concluding that the test is helpful in making an accurate diagnosis in the jaundiced patient. Also in many instances the extent of hepatic dysfunction is suggested. The results of the test on 36 patients with intestinal dysfunction further support the previous conclusion that hypoprothrombinemia develops from lack of adequate food, loss of bile from the intestinal tract or a combination of the two. Most of the 120 patients had hypoprothrombinemia. Patients with relatively severe hepatic damage did not respond to vitamin K therapy while those with obstruction to the common duct practically always responded to adequate therapy. The test can help the physician to determine the severity of hepatic damage in cases of burns, and an early and accurate prognosis can be formulated by repeated tests.

Desoxycorticosterone Acetate for Postoperative Shock.—The results of the preoperative administration of desoxycorticosterone to animals has led Koster and Kasman, among others, to apply the method to 100 selected alternate operative patients. They used the mortality rate as the criterion of the efficacy of the therapy. The mortality rate was 11 per cent among the 100 treated patients and 9 per cent among the controls. Even if reversed, the difference would have no significance. Factors other than shock may have contributed to the deaths in both groups. Therefore since there was no reduction in the mortality rate in the treated group, it may be concluded that desoxycorticosterone acetate had no influence in preventing or in favorably influencing postoperative shock. The enthusiastic reports by other workers of its value for human beings are not supported by the authors' data.

Prophylactic Treatment of Rheumatic Fever by Sulfanilamide—Thomas points out that sulfanilamide prophylactically (from October to June) is effective in preventing recrudescences of rheumatic fever, that it is safe and that if the treatment is stripped to its essentials its cost will be far less than that of caring for the cardiac morbid that the rheumatic subject will eventually become. An effort should be made to treat early every person who has had rheumatic fever with small daily doses of sulfanilamide and to continue the treatment for years. There are more than a million persons in the United States who have suffered from rheumatic fever, 40,000 of them die each year of the disease. To postpone the inauguration of a program for combating rheumatic fever with prophylactic sulfanilamide until after the war would be to lose sight of the immediate importance of this public health problem.

Complement Fixation in Malaria—According to Dulaney and her associates, 102 of 125 patients with malaria parasites in blood films gave a positive complement fixation test for malaria with Plasmodium knowlesi antigen Approximately one third of them had received some treatment before the blood for the tests was obtained Positive tests were obtained from 15 of 192 presumably malarious patients with negative blood films Malaria could not be ruled out in this group The complement fixation and blood film test agreed in 88 per cent of the cases when the two tests could be compared simultaneously Likewise twenty-four positive complement fixation tests were obtained from 170 presumably nonmalarious patients, eighteen of the serums came from patients known to

have leprosy, amebic dysentery or Chagas' disease Seven of 188 normal persons gave a nonspecific reaction Complement fixation using the P knowlesi antigen may prove useful as a supplementary test to the blood film

Hematologic Values for Normal Healthy Men—The level of all the blood elements was determined by Hamre and Au of 137 normal male university students from 16 to 25 years of age Significant differences as to age and race in the blood values did not occur The mean values for the various blood elements for these men of the Hawaiian Islands were comparable to those for men of other geographic regions given by other investigators Therefore particular or peculiar types of normal blood values do not exist for adult men of the Hawaiian Islands

Recovery of Rabies Virus from Brain—Schaeffer and Leider recovered rabies virus from a person the cause of whose death was obscure The presence of virus in the brain in this undiagnosed case was established by animal passages, by demonstration of Negri bodies in the brains of inoculated animals and by immunologic methods Following the recovery of virus further investigation revealed a history of dog bite and other data pertinent to rabies in a person whose antemortem diagnosis was "psychoneurosis and acute anxiety" The need exists to be ever mindful that atypical cases may occur in communities in which rabies is endemic

Sarcoidosis—Three cases of sarcoidosis are reported by Rakov and Taylor to illustrate how easily the microscopic picture may be mistaken for tuberculosis by the pathologist who is not familiar with the disease, which has a predilection for the lymphatic system without cutaneous manifestations In case 1 only after a series of sections of tonsils removed five years previously was reexamined was a single milary sarcoid demonstrated In case 2 studies were not permitted and the authors were unable to observe at microscopy the nonpalpable glands or tonsils In case 3 many signs and symptoms of a disseminated tuberculous process were presented Subsequent study proved the diagnosis of milary tuberculosis to be incorrect Reexamination of previously extirpated lymph nodes established the true diagnosis Since generalized Boeck's sarcoidosis is usually a benign, nonfatal disease, there is no doubt that many reported cures of milary tuberculosis are instances of recovered sarcoidosis The authors urge that all apparent cases of noncavitating tuberculosis be studied with sarcoidosis in mind

Beriberi Heart Disease and Pulmonary Embolism—

Hussey and Katz present 3 fairly typical cases of beriberi heart disease in young men who drank heavily ate little had evidence of associated vitamin deficiency states and had no other apparent etiologic factor for their heart failure Symptoms and signs of heart failure were obvious Two of the patients recovered from their initial heart failure and remained well until they resumed drinking and abstaining from food The third patient, who died in his first attack, had shown considerable improvement when fatal pulmonary embolism to the right lung developed His failure to improve more rapidly was probably due to a large infarct in the left lung In 2 of the cases pulmonary embolism arising apparently from a mural thrombus in the right side of the heart was the immediate cause of death In the other 1 a postmortem examination was not made, but the description of the death suggests pulmonary embolism more strongly than the idiopathic vasomotor collapse of beriberi With one exception (Dock, 1940) there is no reference in the literature to the existence of mural thrombi and embolic phenomena in beriberi heart disease Dock suggested that some cases of idiopathic cardiac hypertrophy may represent beriberi heart disease Embolism may be a more important feature in beriberi heart disease than is generally appreciated The arm to tongue circulation time in 2 cases was moderately prolonged and in 1 the prolongation was severe The circulation time depends on several variables, the cardiac output the state of the arteriolar bed and the venous pressure Probably when the cardiac output is fairly well sustained and the arterioles are wide open the circulation time will be relatively normal and the venous pressure high As these conditions may occur in beriberi heart disease and in other etiologic types of heart disease they are not diagnostic for any one type Furthermore, when the variables are differently arranged in beriberi heart disease the circulation time will be greatly and constantly prolonged

Blood Stream Infection of Cortex of Kidney—Non-tuberculous infection of the renal cortex due to invasion by pus producing organisms is a distinct and important clinical entity, according to Gibson. It is difficult to diagnose, as the clinical signs are obscure and urinary symptoms are absent. As a consequence the condition is frequently not recognized, and its complications—renal carbuncle and perirenal abscess—are rarely diagnosed until a high morbidity has been produced. In most cases the invading organism is *Staphylococcus aureus*, which reaches the kidney by the blood stream from some peripheral infection. A careful search for peripheral infection affords the best diagnostic aid. It is distinguished from pyelonephritis by the relative lack of urinary symptoms in proportion to the severity of the illness and by the fact that in cortical abscess the *staphylococcus* is more likely to be found in the urine.

Arachnodactyly (Marfan's Syndrome)—Barron discusses the symptoms of arachnodactyly found in a family group, in addition to the arachnodactyly 1 member also had recurrent lymphocytic meningitis. This patient was the youngest of a family of 8, 6 of whom presented symptoms of arachnodactyly. The disease had apparently been inherited from the mother's side of the family, probably as a prominent mendelian characteristic. The mother and 4 of her 9 siblings had some symptoms of arachnodactyly. The maternal grandfather and at least 4 of his siblings are also believed to have had some feature of the syndrome. Four of the siblings of the present family had ectopia lentis. Of these 4 1 had a left lumbar scoliosis of the spine, while another had had two acute attacks of lymphocytic meningitis and some chronic symptoms suggesting involvement of the central nervous system. There is no proof that the concurrence of meningeal and arachnodactylos symptoms was a coincidence or that the two chronic conditions were associated. The author cites the case in the hope of adding to the knowledge concerning the development of arachnodactyly. It is suggested that the pediatrician, the orthopedist, the ophthalmologist, the internist and the neuropsychiatrist should have the symptoms of arachnodactyly in mind so that patients may not be unsatisfactorily treated for isolated clinical symptoms such as malnutrition, spinal curvature or apparent mental deficiency.

Lesions of Vitamin A Deficiency—During the course of treating vitamin A deficiency, Straumfjord has observed that not only the lesions of follicular hyperkeratosis but other lesions, at the present time not attributable to vitamin A deficiency.

such as corns, keratosis and acne vulgaris, disappeared. A histologic feature common to these conditions is a local increase in cornification. The incidence of the common cold and the course of chronic sinus infection are likewise so definitely influenced when 100,000 units of vitamin A is given for two years or more that it is difficult to escape the conclusion that insufficient intake of vitamin A plays an important part in their pathogenesis. The follicular hyperkeratosis occurs on the back, elbows, buttocks, calves of the legs and posterolateral aspect of the thighs and arms. These are the areas on which the weight of the body rests during sleep and in which the supply of blood and vitamin A is diminished. Other areas involved are those subjected to mechanical pressure, that is, pressure from shoes and clothing. The disappearance of corns and callosities has been so regular that it cannot be ascribed to fortuitous changes in footwear, occupation or other such factors. However, the rate of response is extremely variable. At times, massive desquamation is relatively rapid, but usually the effect is not observed until a lapse of many months to two or three years. Many other agents affecting the peripheral circulation can be readily conceived of as affecting the cutaneous supply of vitamin A. General tests for vitamin A deficiency have value only when they are positive. When the tests are negative they will not exclude the possibility of local sites of vitamin A deficiency.

Cancer of Lung in Infancy—Only 1 case of primary carcinoma of the lung in infancy was found among more than 14,000 necropsies performed at Cleveland City Hospital in the last twenty-eight years. The patient, an infant of 17 months, Hauser states, had been ill for five months and the true nature of the disease was not suspected. On the basis of a diagnosis of "whooping cough" the child was sent to the contagious ward of a hospital, and bronchopneumonia was diagnosed. If a roentgenogram had been made, there might or might not have been enough evidence to suggest the presence of a new growth, for even later, when the lesion was well advanced, the roentgen signs were interpreted as due to pleural fluid. The autemortem clue to the diagnosis came when attempts to aspirate the left pleural cavity proved ineffective. It seems more probable that primary bronchogenic cancer in infancy develops on a congenital basis rather than on an acquired one. Avitaminosis A and influenza infections may be factors in causing metaplasia of bronchial epithelium with subsequent development of cancer. The logical treatment is early surgical extirpation.

Chronic Leukemia—Pascucci presents an analysis of 64 patients with myeloid and 64 with lymphatic leukemia given roentgen therapy at the Presbyterian Hospital between 1919 and 1940. The usual supportive measures, the most important of which was transfusion, were employed when indicated. The treatment was in all cases individualized, as the aim was not only to reduce the leukocytes and to shrink the palpable masses but also to maintain the patient in an optimal state of well being and efficiency for as long a period as possible. The average age of the patients with myeloid leukemia was 41.1 years and of those with lymphatic leukemia it was 49.6 years.

The 64 patients with myeloid leukemia were equally divided between males and females, and of those with the lymphatic type 37 were men and 27 were women. Weakness and loss of weight were about one and a half times as frequent in the patients with myeloid leukemia as in those with lymphatic leukemia. About one third of all the patients complained of fatigue, less than one half of those with myeloid and one fourth of those with lymphatic leukemia presented some symptom related to splenic enlargement and the first complaint of 63 per cent with lymphatic and 20 per cent of those with myeloid leukemia was enlargement of the superficial nodes. The size of the spleen and the presence or absence of lymphadenopathy are not reliable evidence for differential diagnosis although they do occur frequently. Fever, hemorrhage, retinitis and cutaneous involvement are other signs. According to the initial blood picture the patients with chronic myeloid leukemia when first seen were more seriously ill than those with chronic lymphatic leukemia. A differential diagnosis should not be made purely on clinical grounds without the aid of hematologic studies. The average duration of life from onset of symptoms in chronic myelogenous leukemia was two and a half years, and for chronic lymphogenous leukemia it was two and eight-tenths years. Although remissions were effected whereby the patient's comfort and efficiency were improved, there is no positive evidence that the average duration of life in chronic leukemia was prolonged by roentgen therapy. A short survival period is probable in chronic leukemia if the initial erythrocyte and platelet counts are extremely low. Chronically, the duration of symptoms before medical aid is sought, has a definite deleterious bearing on survival.

Myiasis Due to Warble Fly—Harrell and Moseley discuss the infection of man and animals by larvae of *Dermatobia hominis*, or the warble fly, which is common in the tropics and subtropics of the Western Hemisphere. The disease is easily recognized from the patient's history and inspection of the lesion. The history is that of a moderately tender gradually enlarging furuncle-like lesion with sharp neuralgic-like pains accompanied by the sensation of something crawling beneath the skin. The lesion is dome shaped, and its center is pierced by a crater-like orifice from which bubbles arise. At times the spiracle of the larva may be seen to protrude and with draw through the opening. Often at the periphery a smaller deep mass may be palpated, this being the parasite itself lying in the subdermal tissues. The lesion, in comparison to a true furuncle, is only moderately tender. For successful treatment the larva must be completely removed and the invaded tissue cleansed of its toxic metabolic products and devitalized tissue debrided. The subcutaneous injection of procaine hydrochloride anesthetizes the parasite and renders complete surgical excision less difficult and painless. Suppuration does not follow such treatment. The authors 2 cases illustrate the difficulties that

may be encountered and the depth and vital tissues that the larva may burrow in. In a white soldier with a lesion over his left knee cap and one on the posterior aspect of the right lower leg the parasite had burrowed into the prepatellar bursa and surgical extraction would have been difficult if the parasite had not been anesthetized. Examination of a white soldier with a small lesion in the right groin revealed a small furuncle-like lesion with a central crater overlying the right spermatic cord just above the scrotum. The larva was lying on the spermatic cord just below the external inguinal ring. If anesthetization had not been carried out in each instance, the simple excision might have turned into an extensive surgical exploration of the prepatellar bursa and spermatic cord.

Staphylococcus Food Poisoning—The symptomatology of staphylococcus food poisoning, Slocum points out, is sufficiently significant to differentiate it from *Salmonella* food poisoning. The incubation period of staphylococcus food poisoning ranges from one to eight hours, but more often between two and four hours. The onset is usually characterized by abdominal cramps or pain and nausea, followed by vomiting and diarrhea. The acute stage usually lasts six to eight hours. The temperature is usually normal or subnormal. Recovery is rapid once the acute stage is past and, except for weakness, normal activities may be resumed within twenty-four hours. By contrast, food borne *Salmonella* infection is characterized by an incubation period of six to twenty-four hours, the acute stage is of longer duration and is characterized by fever. Recovery is delayed for several days. The microorganisms of the *Salmonella* group appear to be the causative agents in many European outbreaks of food poisoning but are rarely involved in outbreaks in this country. The ubiquity of staphylococci in nature precludes their complete exclusion from food products. Proper refrigeration is an important measure for preventing the production of enterotoxin in contaminated food products but as mishandling in the home cannot be eliminated the control of staphylococcus food poisoning is practically limited to measures which will curtail an outbreak once it has occurred. Sound sanitary principles in the production of food are effective in eliminating contamination. Outbreaks are usually caused through improper handling of locally produced perishable products and are not within the jurisdiction of the Food, Drug and Cosmetic Act. Little is known about the sources of food poisoning staphylococci, largely because it is difficult to differentiate enterotoxic from non-enterotoxic strains. Knowledge of the source, distribution and conditions required for the production of staphylococcus enterotoxin may lead to some measure which will be of value in controlling this prevalent type of food poisoning.

Milk Borne Outbreak of Gastroenteritis—Terzich discusses the outbreak of food poisoning that occurred in the southwest and northwest sections of Oklahoma City and bordering communities in July 1941. Investigation concerning the type of foods consumed by the nineteen affected families with 71 cases revealed that the families had partaken of milk purchased from two retail milk outlets of the 'gallon jug' variety, which came from the same milk plant. There probably were as many unreported cases. Some member of the affected families had purchased fluid milk at one of the outlets between 5 and 7 p m of the evening of July 1. In most instances the milk was consumed with the evening meal, in a few it was held over until the next morning or was used later the same evening. From two to four hours after each individual had partaken of the milk he became violently ill. At approximately 9 o'clock that evening calls for ambulances and requests for immediate medical care started reaching hospitals and physicians. All evidence pointed directly to the milk as the causative factor. In each household where any portion of the milk was still on hand a sample was secured, as were samples from both outlets, and laboratory study revealed it to be highly contaminated. The milk had not been properly pasteurized, hemolytic staphylococci, toxin producing cocci and coli aerogenes were shown to be present. A large amount of neutralizer

carbonates, had been added to the milk. The plant which supplied the milk employed inadequate pasteurization equipment for the processing of that portion of the milk shipped to Oklahoma City and vicinity. The subsequent contamination of the milk was believed to have been due to an employee with infected cutaneous eruptions on his hands, arms and face who capped the containers by hand.

Plasma Protein in Shock—The fact that concentrated plasma is able to increase the blood volume in severe post-hemorrhagic and traumatic shock was demonstrated by Muirhead and his associates on 20 dogs in the posthemorrhagic shock group. Sixteen of the animals received concentrated plasma and 4 normal plasma. That concentrated plasma caused hemodilution in each case was reflected by a drop in the specific gravity of the whole blood and a decrease in the erythrocyte count, hemoglobin concentration and hematocrit reading. In several instances hemodilution occurred within five minutes after the injection of the plasma. During the hemodilution the specific gravity of plasma remained about the same, meaning that fluid was withdrawn into the circulation. The elevation in the blood pressure paralleled this hemodilution. Normal plasma produced similar results. The response of several animals was unfavorable, this was characterized by rigor, lack of elevation of the blood pressure or even sudden death. In subsequent experiments on normal unanesthetized animals it was observed that all effects followed rapid intravenous injection of concentrated plasma and that the small quantity of soluble pentobarbital (given donor dogs) in the plasma was also a factor. As a final check, dog plasma containing citrate-soluble pentobarbital was dialyzed at low temperature against isotonic solution of sodium chloride. After sufficient dialysis the plasma did not produce ill effects.

Shock in Animals Under Anesthesia—Kendrick and Uihlein performed experiments on dogs with ether and pentobarbital anesthesia. Their results indicate that as little as 10 mg of soluble pentobarbital per kilogram of body weight was effective in delaying the decline of the blood pressure to a shock level even though intestinal manipulation and ether anesthesia had caused a concentration of hemoglobin indicative of impending shock. It was again demonstrated that the spleen is an impor-

tant factor in causing an apparent hemodilution following the injection of soluble pentobarbital. The blood pressure was more rapidly reduced to a shock level in the splenectomized than in the nonsplenectomized dogs. The reservoir function of the spleen was probably its chief contribution. In the absence of the spleen the injection of soluble pentobarbital delayed the decline of blood pressure to a shock level. The effective mechanism of the soluble pentobarbital is not known. The animals in which shock was delayed the longest were those given the smallest doses of soluble pentobarbital.

Concentrated Plasma Protein Solutions for Hematogenic Shock—Muirhead and his co-workers discuss the type of shock in which there is a decrease in the effective circulating blood volume due to an actual depletion of the blood volume itself brought about by loss of whole blood, loss of plasma fluid into the tissues through damaged capillaries or by both factors. Block has termed this hematogenic shock. The cause of the shock can be frequently differentiated on the basis of the preceding events and the physical signs presented by the patient. The proper use of fluid therapy intravenously requires an understanding of the distribution of fluid in the body and a knowledge of the abnormal changes occurring during hematogenic shock. The fluids in the body are cellular, interstitial and circulating. In spite of complications in shock the deficient blood volume must be adequately and rapidly replenished if shock and complications are to be overcome. The solution best capable of accomplishing this should at least increase the blood volume rapidly, encourage a greater cardiac output and peripheral volume flow, be retained in the vascular system, reverse abnormal physiologic mechanisms, be accessible, be easy to handle and to administer rapidly and should have no harmful post transfusion consequences. When concentrated protein solutions are used, new vigor seems to be added to fluid therapy. Concentrated protein therapy is the same whether concentrated plasma, concentrated serum or concentrated albumin solutions are used. The rationale for all these solutions is that by the increased osmotic properties such solutions encourage the entrance of fluid into the blood stream in the early phases. Later, when fluid appears to shift into cells, the concentrated solution tends to reverse this shift. Experimental evidence suggests that cellular water is available for the increase of plasma volume in normal animals when concentrated serum is injected intravenously. Problems concerned with the therapeutic effectiveness of concentrated solution the possibility of reactions and the possibility of harmful dehydration must be completely answered before this type of therapy is generally accepted. Harmful dehydration following concentrated plasma therapy has been overemphasized in the past. Treatment in the early phases of the oligemia is urged.

Significance of Heart Murmurs in Candidates for Naval Aviation—Of 100 naval aviation candidates referred for an opinion as to their cardiac status because of heart murmurs, Mitchell considered the condition in 80 to be functional. Of the 20 with an organic disorder 2 had definite mitral stenosis, 2 hypertension and 1 complete heart block. If these were eliminated from the material studied the percentage of func-

tional cases would be still higher. The 80 subjects were passed for flight training. Ordinarily heart murmurs are not difficult to gauge if organic states are ruled out first. If the murmur is systolic in time, not loud or harsh, is heard only in certain positions, if it is superficial and related to respiration or if it is absent when the breath is held, it is typically functional. The greatest danger of mistake at examination is caused by beginning with auscultation of the heart and ignoring other considerations. A café au lait complexion, distention of veins in the neck, abnormal pulsations, displacement of the cardiac apex beyond the nipple line, precordial heaving or prominence are all significant signs to be noticed by inspection. Inspection is still the most effective means of diagnosis.

Growth of Fibroblasts in Serum Containing Sulfathiazole—Experiments determining the direct influence on leukocytes and fibroblasts of sulfathiazole in concentrations likely to be encountered in locally treated wounds were carried out by Reed and his co-workers. Their results and those of other investigators suggest that, during the time when the exudate of the wound is saturated with the drug, fibroblasts will not grow into the lumen of the wound. In the tissues in close proximity to the actual opening of the wound the concentration of sulfathiazole will at all times permit normal growth of the fibroblasts. As the concentration of the drug in the opening of the wound falls by absorption to slightly below 100 mg per hundred cubic centimeters, a normal growth of the fibroblasts may be expected throughout the entire area of the wound.

Phagocytosis by Leukocytes—Reed and Orr determined what in vivo and in vitro influence sulfonamide derivatives used locally in the treatment of wounds in mice had on phagocytosis by leukocytes. Phagocytosis was determined essentially with the technic devised by Welch and Hunter for determining the toxicity of antiseptics. In vitro concentrations of 8 mg and 80 mg per hundred cubic centimeters of five compounds did not have a significant influence on phagocytosis. On the other hand, supersaturation slightly reduced phagocytosis, this was evinced by the reduction in the leukocytes which take up bacteria and in the bacteria phagocytosed by the leukocytes. As phagocytosis provides a measure of cell activity, leukocytes are evidently not seriously injured by the high concentrations. There was no evidence to suggest that the compounds used stimulate phagocytosis. For the in vivo experiments white mice were given 10 mg of sulfanilamide or sulfapyridine intraperitoneally and then 0.5 cc of a twenty-four hour broth culture of *Clostridium perfringens*. Control mice not given either drug were similarly inoculated. After fifteen minutes, two hours, four hours and six hours the amount of phagocytosis was deter-

mined in fifty random fields. The rate of phagocytosis was highest both in untreated controls and in the treated animals at two hours. At four and six hours the rate of phagocytosis was lower. This was probably due to presence of fewer bacteria to be phagocytosed. However, of most importance is the fact that during the six hours more phagocytosis occurred in mice given sulfanilamide or sulfapyridine than in the control animals. Two groups of guinea pigs were examined for phagocytosis by leukocytes, one after being inoculated with *Cl. welchii* and treated locally in the experimental wounds of the thigh with 0.15 Gm of sulfathiazole four hours after inoculation and inoculated with *Clostridium sordelli* and similarly treated. The number of bacteria in the untreated wounds increased in contrast to the stationary or decreasing numbers in the treated wounds. The proportion of leukocytes in the exudates of treated wounds which showed phagocytosed bacteria was definitely higher than in control wounds, notwithstanding the fact that less bacteria were available for phagocytosis in the treated than in the untreated wounds.

Undescribed Infectious Exanthem—During the last five years Blake and his associates encountered 11 patients with an unidentified acute febrile illness. There were 3 in a family of 5 members. The disease is characterized by fever, no prostration, malaise, a red brown maculopapular cutaneous eruption varying degrees of general lymphadenopathy, splenomegaly and leukopenia with relative lymphocytosis but without any consistent pathologic cytology. It occurred predominantly in the spring and fall. Only 2 were children. The 3 patients in the one family had intimate contact with goats but the other 2 members did not. In the other cases no animal exposure was found. No definite conclusions could be reached regarding the incubation period or a possible animal vector. The period of invasion, calculated from the day of symptoms to the appearance of the rash, varied from two to fourteen days with an average of about six days. The major symptoms during this period were fatigue and general malaise, generalized aches and pains, fever, chilly sensations or a shaking chill, headache, anorexia, occasional nausea and vomiting, and sometimes a mild sore throat, conjunctivitis, photophobia and painful motion of the eyes. The only specific observation about this stage of the disease was the absence of prostration. The clinical course was invariably benign with prompt, uneventful, recovery, there were no complications. There was a moderate loss of weight in 2 and mild fatigue that lasted for a week or more following recovery. Leukopenia or a low normal leukocyte cell count was always seen, and in the latter part of the disease a relative lymphocytosis usually occurred. The leukopenia was usually replaced by a return to a normal total count but never by a leukocytosis. The blood smear was never particularly abnormal, although the lymphocytes were occasionally referred to as large and young. Anemia was not present, and the urine was not abnormal beyond an occasional febrile albuminuria. Agglutinations against Eberthella typhosa and paratyphosa A and B, Brucella, Proteus X 19 and sheep cells were uniformly negative. Blood, stool, urine and throat cultures were negative. The Kahn test was negative. In the differential diagnosis typhoid, infectious mononucleosis, influenza, brucellosis and Rocky Mountain spotted fever must be considered.

Glomus Tumor—Ottley reports the occurrence of a glomus tumor in an uncommon site, the neck. The patient a man aged 38 stated that ten or twelve years before he had a boil on the back of his neck, which was incised. Ever since he had noticed a small swelling at the site of the incision which slowly increased and was always acutely sensitive to touch. Its mere contact with the collar provoked severe pain shooting up the back of the head. On palpation a slightly raised, blue cystic globule looking like a small whortleberry embedded in the skin was found to be the superficial part of a considerably larger firm, rounded tumor lying in the subcutaneous tissue. A diagnosis of glomus tumor was made, and the mass was shelled out from the subcutaneous fat and removed with the attached ellipse of skin.

Lesions of Male Breast—Scarff and Smith record the incidence and microscopic picture of the various types of lesion in the male breast for which mastectomy has been performed. Their material consists of 65 specimens from partial or total mastectomy in the male. Two of them are of particular interest in that they were from workers in diethylstilbestrol, in each of whom hypertrophy of one breast has occurred. There were 15 carcinomas arising in the gland tissue of the breast, 3 sarcomas, 1 rodent ulcer of the nipple, 4 fibroadenomas, 1 lipoma and 41 of chronic mastitis. From this and studies of 2,845 mastectomies on women it is revealed that chronic mastitis occurred in the male twice as often as cancer, the reverse proportions obtained in women, but a degree of epithelial proliferation sufficiently advanced to suggest cancer occurred in cases of chronic mastitis in men only half as frequently as in women. Only 3 breast sections examined and classed under chronic mastitis showed a "dangerous" degree of epithelial proliferation, and 2 of them were from the 2 diethylstilbestrol workers, who had been handling it or its precursors for twelve and ten weeks respectively. Tenderness and enlargement of the breasts was noticed three to four weeks after this work was started and it lasted until it was discontinued, when the symptoms gradually subsided. Biopsies, performed three to five weeks after the

patients had ceased handling the estrogen, revealed a definite degree of epithelial overgrowth in the acini and ducts with, in places, solid acinar formation, but no definite invasion of interstitial tissue by epithelial cells. The only other reference in the literature on the effect of estrogen on the human male breast is that of Dunn, who reports gynecomastia following therapy with diethylstilbestrol.

Differential Diagnosis of Dyspepsia—According to Gill and his colleagues, the conflicting reports of investigation on service cases of dyspepsia depend on differences in the age groups from which the men are drawn and on the varying standards of diagnostic criteria. For an accurate investigation of dyspepsia, gastroscopy and the mucosal pattern technic of roentgenography are necessary. Investigation at special centers is advantageous. The repeated examination of service men with dyspepsia is detrimental to them and fosters the latent neurotic element, it is also uneconomical. Outpatient investigation, being incomplete, is valueless if it proves negative, as the patients drift from hospital to hospital, where contradictory conclusions are often reached because diagnostic standards vary. The formation of special centers for the investigation of men with dyspepsia would solve this problem. Of 217 service patients with dyspepsia admitted to a hospital within three months under comparable conditions only 28.5 per cent showed peptic ulceration, whereas 47.5 per cent had gastroduodenitis, in 16.5 per cent no organic lesion was found.

Salmonella and Shigella Carriers—Vaccaro and his associates attempted to determine the percentage of healthy carriers of salmonella and shigella organisms by cultures of feces from 600 healthy subjects without a previous history of typhoid dysentery or alimentary intoxications. The specimens were obtained by sterile swabs. The various cultures were made immediately so as to avoid the death of the organisms. The culture mediums used were those especially suited for the isolation of the salmonella and shigella organisms. One of them was MacConkey's bile salt agar, while the other two mediums also contained bile salts. The presence of bile salts inhibits the growth of coliform bacilli and at the same time facilitates the metabolism of the salmonella and shigella organisms. The incidence of healthy carriers amounted to 383 per cent, 8 subjects (133 per cent) had shigella organisms and 15 (25 per cent) had organisms of the salmonella type. Of 120 adults examined not one carried the organisms, of 162 children between 6 months and 3 years of age 6 were carriers, and of 318 children between 3 and 12 years of age 17 were carriers. It is of considerable epidemiologic interest that children between the ages of 3 and 12 years constitute the highest percentage of carriers, because habits at this period of life tend to promote dissemination of pathogenic organisms and epidemics. Serum of healthy carriers did not possess agglutinins for the isolated organisms. The serologic test will probably be useful in differentiating healthy carriers from chronic carriers, because the latter often contain specific agglutinins.

Klinische Wochenschrift, Berlin

*Registration of Movements with Photoelectric Reflex Meter. Methods for Registration of Venous Pulse and of Pupillary Reflexes. K. Matthes—p. 295

Sternal Puncture in Diagnosis of Typhoid—Sprenger directs attention to the comparatively high incidence of typhoid in the Polish provinces, stating that in the course of eight months 41 cases were treated at his hospital. Bacteriologic examinations of the blood and excreta and the Gruber-Widal reaction were employed to verify the diagnosis. It was found that in 12 per cent of the cases the titer of the Gruber-Widal reaction was below the level that can be used for the diagnosis. Even higher values deserve cautious estimation when it is a question of the diagnosis. For this reason a bacteriologic verification of the diagnosis must be aimed at in all cases. Blood culture and examination of the feces accomplished this in only 46 per cent of the cases. Since other investigators had obtained favorable results with sternal puncture, the author resorted to this procedure in 16 cases. The culture of the sternal punctate was positive in 12 cases (75 per cent). In 3 instances the diagnosis was verified exclusively by the sternal punctate because blood and excreta remained constantly negative. In 1 case the sternal culture was the first positive bacteriologic result. In 7 cases several sternal punctures were made and blood cultures were set up simultaneously. The sternal and blood cultures did not exhibit uniform behavior, so that dependence of the sternal culture on the blood culture can be excluded. The author concludes that sternal puncture makes possible the bacteriologic verification of typhoid in a much higher percentage of cases than is possible by blood culture

and examination of the excreta. Since sternal puncture involves no danger and almost no pain it should be used in the diagnosis of typhoid just as regularly as blood culture and bacteriologic examination of the excreta.

Registration of Venous Pulse and Pupillary Reflexes with Photoelectric Meter—Matthes shows that with the aid of the prismatic optic of a reflexless electric ophthalmoscope a moving point can be illuminated. It reflects the light to a photoelectric cell behind the prism. The movements of the illuminated point can thus be registered as intensity changes of the photo current. Pulsations of the skin, for instance of the jugular vein, can thus be registered in a simple manner. By using ultrared, invisible light, it is possible to register with this method the pupillary reflexes of the human eye. The latent period of the pupillary reflex can be measured exactly and different types of light reactions of the pupils can be recorded.

Experiences with 2 Sulfamylaminopyridine in Gonorrhea. T. E. Olin—p. 545
Tertiary Syphilis with Unusual Roentgenologic Lung Changes. Case. T. Romanus—p. 565

Benign Lymphogranulomatosis (Schaumann)—Dressler and Wagner direct attention to the systemic entity which Schaumann in 1914 designated as benign lymphogranulomatosis, pointing out that the cutaneous manifestations of this disorder had been known as lupus pernio (Besnier) or as Boeck's sarcoids, but that these lesions are only occasionally present. The authors have given particular attention to the pulmonary manifestations and come to the conclusion that these, together with the general aspects and the course, often permit the diagnosis, although the final proof, the demonstration of the histologic structure, may still be lacking. They have been able to collect 65 cases, some of which were referred to them with the diagnosis Boeck's sarcoid or lupus pernio, and others were sent to them by the ophthalmologic clinic for internal examination. In some of the latter cases it was discovered that the eye disorder was a manifestation of benign lymphogranulomatosis. The authors review 2 cases which are of particular interest not only from the internistic but also from the ophthalmologic point of view. In the first case lungs, eyes, lymph nodes, salivary glands, bones, tonsils and spleen were affected, probably also liver, kidneys and nerves (a paralysis of the nervus facialis may have been toxic). The authors do not know whether an otitis media was accidental or a manifestation of benign lymphogranulomatosis. The diagnosis of benign lymphogranulomatosis could be certified by the characteristic microscopic alterations found in two excised lymph nodes and the tonsils. The examination of the eyes showed a keratitis superficialis and severe iridocyclitis or uveitis, which was partly proliferative, partly exudative. Hemorrhages into the corpus vitreum occurred repeatedly. These were caused by chorioretinitis or periphlebitis retinae and finally disappeared. There remained opaque bands on the cornea, posterior synechias, cataracta complicata, patches of choroiditis and retinitis proliferans. The second case was a typical one of uveoparotitis. The characteristic findings of the hilus lymph nodes, the spleen and the liver were typical for benign lymphogranulomatosis. The authors found patches of choroiditis and periphlebitis and believe that they were the first to observe periphlebitis retinae in cases of benign lymphogranulomatosis. In an addendum to this report they say that after six years the general condition of the first patient is excellent. The swellings at the pulmonary hilus have disappeared, but the milary dissemination has again increased. The ophthalmologic disorder is stationary. The spleen became again palpable and extended 2 fingerbreadths beyond the costal arch. The formerly resistant swellings of the cervical and of the submandibular glands showed a surprising regression during the nine months that followed the tonsillectomy. This regression was a distinct surprise, because sclerotization was suspected in view of their existence for several years.

Book Notices

Influenza A Survey of the Last 50 Years in the Light of Modern Work on the Virus of Epidemic Influenza By F. M. Burnet and Ellen Clark. Monographs from the Walter and Eliza Hall Institute of Research in Pathology and Medicine Melbourne Number Four Paper 1p 118 with 20 illustrations Melbourne & London Macmillan and Company Ltd 1942

From Australia comes this review of information regarding influenza accumulated during the last fifty years. The monograph is supplemented by a good bibliography, well selected to cover the important available literature. The book is also up to date in recognizing the recent research of Horsfall and Lemmette. The authors recognize the possibility that living virus used in inoculation against influenza might actually reach the lung and set up the specific disease. The section on bacterial and virus vaccines states in a brief paragraph the basis of the use of virus products. It says "It is clearly unjustified, however, to try out a method, however convenient its practical application, unless preliminary work shows (1) that it has a high probability of proving effective and (2) that the risk involved in its application is small enough relative to that presented by the pandemic to allow public opinion to accept the procedure. Neither of these probabilities can ever be properly evaluated except as a result of actual pandemic experience, but something can probably be learned from tests on volunteers without necessarily exposing them to natural infection." The authors believe that it is technically possible to prepare virus of any grade of human virulence less than that of the initial material and to use the amniotic method for the preparation of quantities of any of such graded virus strains. The practical problem, therefore, becomes one of finding which, if any, of the infinite number of possible strains has the required characteristics. It is the belief of the authors that the dangers involved in using such inoculations are infinitesimal compared with the kind of devastating epidemic of influenza that swept the world in 1918. Indeed, they feel that the provocation of an epidemic of mild, spontaneously spreading outbreaks of influenza from inoculated subjects would probably be more beneficial than otherwise in extending the proportion of protected individuals. The book also outlines a program from clinical research leading to prevention of the next possible epidemic.

Sex Guidance in Family Life Education A Handbook for the Schools By Frances Bruce Strain Cloth Price \$2.25 Pp 340 New York Macmillan Company 1942

The psychologists, sociologists, economists and physicians have recognized the large part played by sex and our attitudes toward it in modern life. The concealment of previous generations has given place to a point of view which demands education early in life as to reasonable attitudes. The early entrance of women into public work and industry, the programs for planned parenthood, the emphasis on sex in books, plays and motion pictures all tend to focus more and more attention on these problems. Recently one leading metropolitan newspaper found it necessary to conduct a campaign because of increasing instances of attacks on women. One eminent educator has pointed out that sex is the subject above all others about which we are most keen to learn and about which we wish most to know but that it is the one subject on which children have less

opportunity of learning from safe and truthful sources. Surveys made among high school boys and girls indicated abysmal ignorance of some of the most simple biologic facts.

In a sociological research Professor Baker discovered that educators in twenty-seven states considered that sex education should be primarily a function of the home and not of the school. There were only ten states in which there is any encouragement for sex education in the schools. Opposition to such education comes from various agencies including parental opposition, usually resulting from ignorance or misinformation, and in about 5 per cent of instances from religious groups. As in many other fields of education, there is no scientifically conducted research on sex education which could guide instructors as to technique. Other questions concern segregation of the sexes for purposes of sex education and the content of courses on this subject. As a supplement to his book Professor Baker submits outlines of courses now available in various schools and a modern bibliography of the subject.

Among the leaders in the field of sex education have been Ernest R. Groves, professor of sociology in the University of North Carolina, and Mrs. Gladys Hoagland Groves, who has been associated with him in some of his work. More recently there is Catherine Groves, their daughter, who has acted as a marriage counselor and who is now executive secretary of the Family Service Association of Durham, N. C.

The book on "Marriage," first published in 1933, is now offered in a revised edition. It approaches the subject from the sociological point of view, discussing every aspect of the marriage problem and concerning itself as well with many biologic, physiologic and pathologic aspects of the subject. Especially modern in this book is the discussion of childbirth and contraception. Instruction in marriage at the University of North Carolina, in which this book is utilized as a textbook, is now given in seven sections—five for men, one for women and one for men and women together.

The book on "Marriage and Family Life" by Gladys Hoagland Groves is designed not so much as a textbook in the field as it is a book of advice to married couples. Obviously marriage is the basis of the family, so that a large portion of the book is devoted to proper adjustments in family life. Next come questions related to courtship. Thereafter come chapters on the choice of a mate, personal adjustment during the engagement, family finances and the role of the husband and wife in modern marriage. Throughout the book are references to numerous cases in which the author has acted as a marriage counselor. These teach their lessons in an exceedingly interesting form.

In the book called "Sex Fulfillment in Marriage" the members of the Groves family have cooperated, this book emphasizing sex more than either of the other two contributions. In this book also the authors have drawn freely on other work in the field of marriage counseling. They are convinced that sex instruction of children would avoid many of the serious difficulties which have come to them from adults who have been unable to make adequate sex adjustments. The impressions of adolescent life are frequently carried over to adult years and yield avoidable unhappiness. The book follows the usual outline of beginning with childhood problems and carrying the reader through courtship, the beginning of marriage, the sex role of the husband and wife, common marital problems, sex hygiene, birth control, pregnancy and the philosophy of sex. The scientific and yet easily readable approach to this subject makes this a volume that can be widely recommended in its field.

The volume by Frances Bruce Strain is subtitled "A Handbook for the Schools." This book is offered to teachers, personnel workers, counselors and others in the schools to aid them in their approach to the subject. It therefore carries the reader through school experience, family relationships, technique in sex teaching and the development of counseling centers. The chapter on technique in sex teaching is a reflection of actual experiences. Especially important in this chapter is the discussion of the words used in speaking of physiologic and anatomic matters. This chapter is exceedingly practical and should certainly be useful to the newcomer in matters of instruction in the lower grades of school. The bibliography is suggestive of interesting material but hardly complete enough or detailed enough to be most useful.

Acoustically Handicapped Children The Committee for the Study of the Care and Education of Physically Handicapped Children in the Public Schools of the City of New York. Report of the Sub Committee on Acoustically Handicapped Children. Paper. Pp 109 with 2 illustrations. New York: Board of Education 1911

This report of a subcommittee of the Committee for the Study of the Care and Education of Physically Handicapped Children in the Public Schools of New York City has been compiled by a representative group of doctors, social workers and educators. Dr E P Fowler has written a comprehensive, brief but accurate, outline of the types and causes of deafness. Much of the remainder of the report contains tables of findings from hearing surveys made.

Thirty thousand children were examined by the phonograph audiometer, and 1,080 found hard of hearing were given a test with a pitch range audiometer. In the elementary grades, 14 per cent were found to have a 9 decibel or greater loss in one or two ears. The proportion diminished in the junior high schools (10 per cent), Day High (5 per cent) and Vocational High (8 per cent). These figures are so grossly higher than what has been found elsewhere throughout the country over many years as to require an explanation, which is not given. The report significantly admits that "wide variations in the percentage of acoustically handicapped pupils were found among the several schools of the same type." This obviously suggests a high variability in the technique and accuracy of the test as given in the various schools.

The New York survey of 1935 is statistically reported 643,318 children showed between 27 and 35 per cent handicapped by a 9 decibel loss. Yet, in this study, many of the supposedly deafened were not retested, a procedure which always eliminates some of the suspected and further reduces the percentage. (Generally speaking, the many surveys held for years report around 3 per cent affected.)

The committee believes that the discrepancy between the percentages for elementary schools and for secondary schools is due to the dropping out of handicapped children by reason of poor school performance. No data are reported to prove this supposition.

A number of pages of the report are devoted honestly and frankly to the independability of the data collected from the City Day School for the Deaf, Public School 47. "Histories are generally incomplete and inadequate as to previous ear history and dates. Otological examinations are incomplete in a great many cases. Diagnoses appear to have been made wholly on the basis of histories and hearing losses. No otoscopic data are mentioned. Nose and throat examinations were apparently superficial, in many cases none were shown to have been made. There is no evidence of any otological treatment having been given." This "survey" was one conducted between the years 1935 and 1938 as a WPA project under the direction of the board of education.

It is informative, yet disappointing, to read in the summary "There is now no medical or otological service for acoustically handicapped children either under the Board of Education or Department of Health, other than provided in Public School No 47" (the city day school for the deaf). (Recall that the deaf are profoundly handicapped as compared with the hard of hearing.)

The committee's conclusions are distinctly constructive in suggestions for reform, "Provision must be made for the inauguration of otological, medical testing and educational programs for acoustically handicapped children." It is to be hoped that "otological, medical testing" may be expanded into real otologic care for those with incipient deafness, although no suggestion of this appears in the recommendation.

The reviewer takes the liberty to remind the reader that "the world is still deceived by ornament." It might appear that something is being done for the hard of hearing child when one considers the number of hearing surveys that have annually been undertaken throughout the country. This survey from New York City is not greatly different from surveys elsewhere, except in its frankness in admitting that most of the statistics are nearly worthless and that actually nothing of a preventive or therapeutic nature is being done for the deafened child when found. These admissions are the real contributions of this voluminous, costly study and report.

American Red Cross Textbook on Red Cross Home Nursing Prepared Under the Direction of Nursing Service American Red Cross. By Lora L. Trott, R.N., B.S., Assistant Director, Health Education, Red Cross Nursing Service, Washington, D.C. Formerly American Red Cross Textbook Home Hygiene and Care of the Sick by Jane A. Delano, R.N. Paper. Price 60 cents. Cloth. Price \$1.10. Pp 431 with 103 illustrations. Philadelphia: Blakiston Company 1942.

This is the fifth edition of a book first published by Jane A. Delano in 1913. It has been revised and brought up to date by several competent authorities and it has had the cooperation of great numbers of workers who have done their utmost to aid the Red Cross in making this a practical working book. Every home maker can keep herself and family in good health if she will learn the simple facts here made available. The book is divided into four units, the first two of which discuss the problems involved in making health and happiness in home life and in the community, the third unit is devoted to the problems of the mother and the child, and the fourth explains how one may cooperate intelligently with the physician when sickness invades the home. The amount of material here assembled is large and authentic. It is supplemented by a reading list and an index, as is each section of the book. There are also questions for review. If any criticisms are to be made they concern the inadequacy of the illustrations, the lack of inspiration in the type and in the display of the material and the general dreariness and solidity of the presentation. It is like a meal which is full of nutrition but somehow lacks those qualities that stimulate appetite. There are, however, occasional sections which utilize modern teaching methods to great advantage, for instance, the section on the care of the patient at home in the chapter on how to take care of a person who has a communicable disease is told as a story of a family in which an infectious disease appeared. This is interesting and instructive. Altogether the book can be especially recommended because the price is most reasonable, it is quite reliable and, if suitably studied, it must result in quite advances in personal and public hygiene in our nation.

The Care of the Aged (Geriatrics) By Malford W. Thewlis, M.D., Attending Specialist, General Medicine, United States Public Health Hospitals, New York City. Fourth edition. Cloth. Price \$7. Pp 589 with 50 illustrations. St. Louis: C.V. Mosby Company 1942.

A new specialty devoted to the care of the aged is called geriatrics. Pediatrics and geriatrics are what might be called "horizontal" specialties in contrast to such "vertical" specialties as ophthalmology, dermatology or gynecology, which are devoted to disease of restricted anatomic structures or regions at any age. Certain diseases or degenerations have been comparatively neglected in the aged. If they could be brought into focus and properly studied only by the development of a group of specialists particularly interested in such problems there would be ample justification for a new specialty. At present there seems little evidence to indicate that the problems peculiar to the aged cannot be investigated satisfactorily by physicians adequately trained in general practice, internal medicine, neurology and other fields without resort to a new "specialty." The material in this book which is strictly applicable to the aged could be compressed into a fraction of the space now employed. This is not to minimize the importance of disease in the aged, whose peculiar problems have in many cases received scant attention from busy physicians. Nevertheless it is doubted that there is at present enough information on the subject to warrant a special textbook.

Everyday Nursing for the Everyday Home By Ellnor E. Norlin, R.N., Teacher of Hygiene and Home Nursing, Julia Richman High School, New York, and Bessie M. Donaldson, R.N., Teacher of Hygiene and Home Nursing, Bay Ridge High School, Brooklyn, N.Y. Cloth. Price \$2.50. Pp 306 with illustrations by Mary Simas. New York: Macmillan Company 1942.

This book, written by two teachers of hygiene and home nursing, is a useful and clearly written work. It emphasizes preventive health measures and is well oriented with respect to mental health. The health needs of the growing child are emphasized in the first half of the book. The latter half of the book is devoted to the actual nursing needs during illness. Throughout the book, in presenting methods and techniques for care of the young or of the ill, that meticulous attention to detail characteristic of well trained nurses is evident. This book should be useful in the home and to doctors and nurses in informing and advising the layman.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SEASONAL FREQUENCY OF DEATHS FROM APOPLEXY

To the Editor—The question has come up as to what time of year apoplexy is most likely to occur. That is, is it more prevalent in the summer or winter months? Some one has the idea that apoplexy occurs in the month of August more than in any other month. I would appreciate any information you may furnish on this.

H. Quillian Jones, M.D., Fort Myers, Fla.

ANSWER—Apoplexy deaths occur most frequently in mid-winter cold and are at a minimum in August and September here in America. In Florida such deaths are 64 per cent more frequent in January and February than in August and in September, in Alabama 39 per cent, in Virginia 37 per cent and in New York 36 per cent. The accompanying table tells the story.

Deaths from Cerebral Hemorrhage and Softening

(Five year average 1931-1935 thirty one day equalized month basis)

	January	February	March	April	May	June	July	August	September	October	November	December
Florida	92	105	86	78	69	66	67	59	61	61	78	91
Alabama	100	93	98	79	80	86	72	63	70	79	86	95
Virginia	144	139	137	136	192	190	115	105	101	10	130	178
New York	826	822	796	784	741	693	694	598	616	694	730	801

PLACENTA PREVIA

To the Editor—A woman aged 29 in her first pregnancy suffered rhythmic pains, with moderate bleeding and discharge of fragments of material found to be decidua and free of chorionic villi just one week before completion of the seventh month. After all fragments were expelled the pains subsided and pregnancy continued another six weeks. An anterior marginal placenta previa was found, but labor was without incident and at no time was there more than the normal amount of loss of blood. Two and a half years later in her second pregnancy the same condition recurred—again just one week before the completion of the seventh month. This time the pregnancy was carried only another ten days. At labor an anterior marginal placenta previa was again found no incident occurred and there was no excessive amount of bleeding. The baby lived only one day because of prematurity. Relevant points in the history are the presence of a compensatory lordosis due to childhood poliomyelitis affecting the left hip and thigh and the possible presence of an intramural fibroid just above the internal os. Is this train of events typical of placenta previa? What investigations would be suggested in this case? Can the patient be assured that the condition will be unlikely to recur? What treatment would be indicated to prevent such an occurrence in the future?

M.D. Ontario

ANSWER—Repetition of placenta previa in the same patient is not an infrequent occurrence. In fact, some cases of habitual abortion are due to this condition. Unfortunately, at the present time there are not any means of preventing low implantation of the fertilized ovum. Most likely, the old poliomyelitis and present intramural fibroid have nothing to do with the development of the placenta previa. The occurrence of painless bleeding in the seventh month is characteristic of placenta previa. Since there is no known way of preventing this condition, the patient should be kept in bed most of the time after the sixth month. However, even complete rest in bed may not prevent the occurrence of bleeding, because the bleeding is due to partial separation of the placenta. This is the result of the physiologic thinning out of the lower uterine segment, during the process of which there is some "shearing off" of the placenta with resultant bleeding.

PAINTING LEGS

To the Editor—Is painting the legs or applying a lotion in place of silk hose harmful?

Juanita S. McLaughlin, M.D., Mercersburg, Pa.

ANSWER—Information available indicates that a great many liquid stocking preparations on the market should be entirely harmless when used as recommended. This statement could not be made of some of them, however, because some contain coal tar dyes.

A PROBABLE HIATUS HERNIA

To the Editor—At the age of 25 a man who is now 36, 5 feet 10 inches (178 cm) tall and weighing 195 pounds (88.5 Kg), noticed precordial pain which had no relation to exertion. The pain was dull and would continue for several hours rarely, sharp spasms of pain lasting for a second would occur. There was no feeling of constriction or very severe pain. The pain was absent or decreased during exertion. The site of the pain was in any one of three places—over the aortic area, at the apex or about 2 inches to the left of the apex and occasionally the pain was referred to all fingers and the left arm. The fingers most commonly feeling numb were the thumb, the index finger and the middle finger. During the past year the pain has been more severe and more constant although there was a period of three months two years ago during which the pain was absent. The patient at this time was very busy and overworked otherwise there was little change in his mode of life. Smoking, has a curious effect on the pain giving rise to it quickly after two cigarettes are smoked. If many cigarettes are smoked afterward there is no pain or occasionally it continues. The pain occasionally is decreased by glyceryl trinitrate and sometimes is not affected. The patient does not now smoke and says he feels better but the pain continues. After he discontinued smoking the pain entirely ceased for about five days and then came back. The physical examination is negative. The chest is clear by x-ray examination except for a 'furry' outline of the pericardial sac. The heart is not enlarged. The pulse rate varies from 70 to 100 at rest. The heart sounds normal except for a 'split' first sound at the apex and occasional extrasystoles. The blood count is normal. Eight Wassermann tests have been negative. There have been three electrocardiograms. The first two were normal in all four leads except for somatic tremor and extrasystoles, the last electrocardiogram showed a split T wave in the third lead. The first was taken ten years ago, the second four years ago and the third two months ago. All tracings were pronounced normal. The patient is in good general health except for an irritable colon which gives a chronic diarrhea without blood. This can be controlled by a soft diet. He drinks coffee but discontinued it for three months with no effect on the pains. Reflexes are normal except for absent knee jerks which have always been lacking. The patient has been seen by three cardiologists all of whom said that he does not have heart disease, one called it a psychoneurosis. I should appreciate advice regarding the probable cause of pain, the necessary tests or procedures and the treatment and prognosis.

M.D. Arkansas

ANSWER—There are several possible causes for these symptoms, and each possibility is in turn rendered improbable by some point in the history.

The subjective symptoms will fit very well into a diagnosis of angina pectoris, but it is difficult to discover just what type of anginal pain would be much better by exertion or would last for hours. Any explanation would be more ingenious than scientific or clinically probable. Anginal pain is occasionally induced by cigarette smoking, but in this case occurrences of pain did not cease when smoking was discontinued.

A hiatus hernia could cause anginal symptoms, either by mechanical displacement of the thoracic viscera or by initiating a reflex vasoconstriction of the coronaries. A hiatus hernia is very rare at the age of 25 unless it is associated with a true congenital short esophagus and is in part a thoracic stenosis. In such a case the symptoms would not tend to disappear over a period of months.

The type of hiatus hernia seen associated with a spastic colon and possibly due to a reflex shortening of the longitudinal fibers of the esophagus, rarely occurs before 40 but does occur in so-called neurotic individuals. The type of hiatus hernia due to increased intra-abdominal pressure also rarely occurs early in life and usually gives a fairly definite history of symptoms on stooping over or lying down after meals. A spastic colon over contracting on gas or fecal matter could cause anginal pain probably because of a reflex coronary vasoconstriction. Such a spastic colon could readily be assumed to be better symptomatically during a period when the patient was busy and his attention diverted from himself. And it might be better on exertion. A therapeutic test with atropine or belladonna, alone or with a barbiturate, should help to decide. Mediastinal tumor of any nature should be ruled out roentgenologically but is improbable with the history of relief on exertion.

It is difficult to think of any neurologic basis for pain with this distribution and with so long a history with no apparent progress. A cord tumor would not be so diffuse in its manifestations and would not be at all likely to be as stationary. It might give a history of being worse on lying down but hardly of being better on exertion. A hemangioma might involve several vertebrae on either side or on both but is too remote a possibility and is ruled out by the history.

While such a patient may indeed be psychoneurotic, no case should be easily dismissed with such a diagnosis. It is better to say simply that one does not know, and not to say that until every possible source of the symptoms, however remote, has been carefully explored and reexplored over a long period.

MASTURBATION AT HIGH SCHOOL AGE

To the Editor—What can be done for masturbation in high school boys? What ill effects might ensue? For the school physician this is a serious problem

M D, Maine

ANSWER—The subject of masturbation in boys of high school age is considered quite differently from a generation ago. At that time it was supposed to be the cause of serious injury to the body, the mind and the spirit.

Practically all authorities are now agreed that it is much less serious than was formerly supposed, and there are now many authorities who believe that it is not serious at all unless it so conflicts with the boy's training and ideals as to cause him to feel seriously degraded and to cause him to worry and possibly to develop some sort of anxiety psychosis.

Standard textbooks of genitourinary disease for the most part treat the practice as being a dangerous one, but today many are strongly of the opinion that those taking this view are simply repeating the conventional teaching of the past. Probably it is better simply to regard masturbation as an emotional release. Certainly it is safer for a boy to practice masturbation than for him to participate in illicit sexual relations.

If we suppose that the practice is seriously wrong still the problem as to what can be done about it is unanswered. The claim that exercise, recreation or heavy employment will remove the desire to masturbate is utterly foolish, because the desire arises mainly when one is in bed, and at such a time one cannot of course be indulging in hard work. As a matter of fact moderate degrees of fatigue in some persons seem to serve as mild sexual stimulants.

A healthy boy in a good home, loved and well cared for by his parents will rarely if ever injure himself by masturbation unless he has been taught that he has degraded his body, lost his soul and undermined his intellect.

The school physician should realize that whatever he does or tries to do, whatever his opinions may be, the practice will probably continue. Where such practice is in the scope of what may be considered normal he will probably do well to ignore the question. Where groups of boys are involved or in instances which seem to be abnormal, special consideration will be required.

PRESSURE POINTS TO CONTROL BLEEDING

To the Editor—I have been interested in first aid work for a long time especially in connection with Boy Scout work and civilian defense first aid training. The teaching and demonstrating of pressure points in controlling bleeding has raised the question in my mind as to its value. In many years of my practice in my two years service during the World War and in industrial work I have never found any occasion to make use of these pressure points. I know of no time that any one practicing first aid has found it necessary or advisable to make use of them. Could you let me know if there has been any study or investigation as to the value of teaching this? Most of the pupils taking first aid find it difficult to find these pressure points.

William Ginsberg, M D St Paul

ANSWER—Any study or investigation as to the value of teaching pressure points for the control of hemorrhage is not known. It is extremely doubtful that these pressure points are ever used by physicians doing a large amount of emergency surgery. Nonetheless it is entirely conceivable that under certain rare combinations of circumstances the trained first aid worker may save a life by his knowledge of the pressure points. This applies particularly to the pressure points of the arm and thigh. The pressure points over the subclavian, the facial and the temporal arteries are of much less value, and the pressure point over the carotid carries additional danger from the possibility of inciting the carotid sinus reflex.

As pointed out in the report of a committee of the House of Delegates of the American Medical Association at its June 1942 meeting, the work of the Red Cross and other agencies which have interested themselves in first aid is commended. Attention was called to the fact that first aid manuals are written by physicians, and the first aid teaching is initially done by physicians, and that cooperation lies in their willingness to render the service and the willingness of the agencies concerned to accept it.

ESTROGEN THERAPY FOR ARTHRITIS

To the Editor—Estrogen therapy (diethylstilbestrol) has been reported as helpful in relieving various arthritic and rheumatic symptoms in women in or many years past the menopause. Would the estrogen be likely to help elderly men with the same complaints?

M D Alabama

ANSWER—It has not been proved conclusively that estrogenic therapy relieves arthritis in women. Therefore there is no reason to believe that it would help elderly men suffering from the same disease.

TREATMENT OF HYPOPARATHYROIDISM

To the Editor—I recently had occasion to review the literature relating to the use of dihydrotachysterol in hypoparathyroidism and thought that I had learned from this literature as well as from personal experience with 1 patient that a distinct advance had been made in the treatment of hypoparathyroidism and that dihydrotachysterol was a specific and unique remedy. However, I now encounter the article by Franklin C McLean (The Journal Aug 23 1941 p 609) in which it is stated that everything that can be accomplished with dihydratichysterol can be accomplished just as well and just as safely with vitamin D provided vitamin D is given in sufficient dosage. Roughly 400 000 units of vitamin D correspond to 1 cc of the 0.5 per cent oily solution of dihydrotachysterol. I wonder if sufficient time has elapsed since the publication of McLean's article for the accumulation of further clinical data on this subject and which one of these two preparations in the light of present knowledge is preferable in the treatment of hypoparathyroidism.

M D Georgia

ANSWER—Severinghaus (Proceedings of the Central Society for Clinical Research, THE JOURNAL, April 11, 1942, p 1322) states that his observations on 3 patients with post-thyroidectomy tetany and 1 with idiopathic hypoparathyroidism confirm the point of view advanced by McLean. The article by McLean referred to in the inquiry also gives a number of references to papers reporting favorable results with vitamin D. In the present state of knowledge it cannot be said that either dihydrotachysterol or vitamin D is superior to the other in the treatment of hypoparathyroidism.

INDICANURIA—DIET AND HYPERTENSION

To the Editor—What is the clinical significance of indican in the urine? Is there any evidence to show that it is related to hypertension or to any other serious clinical condition? What benefit if any is there in garlic therapy for the treatment of this condition? What dietary regimen is recommended for the correction of this condition?

Herbert K Abrams M D Texarkana Ark

ANSWER—Indican is normally present in urine in small amounts. It is increased by a high protein diet, as indoxyl is derived largely from intestinal putrefaction. Thus transient indicanuria may mean no more than indicating a recent meal containing an excess of meat. It is rarely increased by constipation, but stasis of the bowel, such as may occur in typhoid, peritonitis or intestinal obstruction, raises the indican excretion greatly. There is no reliable evidence indicating that indicanuria is in any way associated with hypertensive arterial disease.

There is no valid evidence that garlic or garlic preparations have the slightest therapeutic value in hypertensive disease.

Dietary management of hypertensive patients is not a major factor in the control of the disorder. A well balanced ration, with adequate protein (at least 1 Gm per kilogram of body weight daily), liberal vitamins and minerals and designed to reduce weight in the obese is all that is necessary. Anemia, which is often secondary to iron deficient diets, greatly enhances the ill consequences of the vascular disorder. Particularly important is a free intake of fluids. Unless there are specific contraindications, at least 3 liters of fluids should be consumed daily, the urinary volume for twenty-four hours is best kept at or above 1500 cc. Coffee and tea are permissible, especially in the morning, but should be deleted in the evening as caffeine may interfere with normal nocturnal rest and sleep. Condiments and spices should be omitted from the diet. Salt is permissible in normal quantity, but excessive oversalting is as unwise as unnecessary. Alcohol, in moderation, is desirable, especially for older patients and/or those who exhibit evidences of arteriosclerosis. The essential element in the dietary regimen of hypertension is moderation in all things. The management of this complex disorder involves many approaches other than through nutrition.

BILATERAL ADRENAL DENERVATION

To the Editor—Please advise as to the present status of Crile's bilateral adrenal denervation for neurocirculatory asthenia in which he has reported 94 per cent cures also confirmatory evidence for the value of this operation in hyperthyroidism and peptic ulcer. Crile reporting 93.7 and 96.4 per cent cures respectively.

M D New York

ANSWER—Dr Crile's bilateral adrenal denervation has not been established as of demonstrated value for any disease. Neurocirculatory asthenia is probably a functional disease, ill defined and probably covering a number of conditions. Like other forms of neuroses, it can generally be treated successfully by a well trained neurologist or psychiatrist. There is no confirming evidence for Dr Crile's claims for a high percentage of cures in both hyperthyroidism and peptic ulcers by bilateral adrenal denervation.

"KNUCKLE PADS" AND DUPUYTREN'S CONTRACTURE

To the Editor—A man aged 25 has firm nodules on the dorsal aspects of the proximal phalangeal joints of the right fourth finger, the left fifth finger and the left third finger which appeared spontaneously in that order during childhood, during adolescence and during the past year. There is no restriction of motion in the involved joints but the nodules are tender to pressure and to extreme flexion of the joints involved. Roentgenograms of the joints show no bone deformity and no areas of calcification in the soft tissues. In addition to these lesions there is a firm nodule on the sole of the left foot which was first noticed three years ago and which appears to be associated with the flexor tendon of the big toe. A similar nodule, which appeared six years ago in the palm of the left hand at the base of the fourth finger was diagnosed as an early Dupuytren's contracture, and the palmar fascia was successfully excised ten months ago. Microscopic examination of the specimen confirmed the clinical diagnosis. There has been no recurrence to date and there is no functional impairment of the hand. It is interesting that the patient's maternal grandfather had "drawn in" fingers and that the patient was rowing on his college crew when his Dupuytren's contracture developed, for the condition is commonly attributed either to a familial tendency or to occupational trauma. 1 Are nodules on the phalangeal joints such as I have described, known to be associated with Dupuytren's contracture? 2 Would roentgen therapy be advisable? 3 Is surgical excision the method of choice? 4 What is the prognosis? M D, Maine

ANSWER—1 Yes

2 No

3 Yes

4 Good

A. E. Garrod, an English physician, first called attention to the "knuckle pads" and their common association with Dupuytren's contracture. They often develop before any thickening of the palmar fascia takes place and occur in 10 to 15 per cent of cases of Dupuytren's contraction.

INTRACERVICAL SOFT RUBBER PESSARY

To the Editor—There seems to be coming into more popular use a soft rubber contraceptive pessary which is inserted into the cervix. This pessary has three or four pliable soft rubber inverted cones attached to the stem that is inserted into the cervix. We are told that this contraceptive measure is effective and harmless and that the pessary can be retained for several weeks, having no interference with menstruation. Please inform me as to the correctness of this information. Is the pessary harmless to the cervix? Is it effective? How long may it be left in place? Henry W. Ten Pas, M.D., Holland, Mich.

ANSWER—No material or device is yet known that can long and safely be retained within the cervix or uterus. Soft rubber cannot be cleansed in that position, and pliability does not abolish its being a foreign body. Such devices probably reduce fertility, but their chief actions are as early abortifacients.

SULFATHIAZOLE AND WHOOPING COUGH

To the Editor—What is the influence of sulfathiazole in whooping cough? A girl aged 18 months developed bronchial pneumonia in the third week of pertussis. She was given emulsion of sulfathiazole (5 grains to a drachm) a teaspoonful every four hours (during the day only) until pneumonia was under control. While the paroxysms of coughing were extremely severe prior to the administration of sulfathiazole, they were greatly reduced on exhibition of this drug and the course of whooping cough seems greatly modified.

E. Ray Royer, M.D., North Salem, Ind.

ANSWER—Sulfathiazole is used routinely in some contagious disease hospitals for the treatment of whooping cough patients suffering from complications. Under such circumstances there seems to be no question with regard to its value. It is doubtful whether sulfathiazole can be depended on to exert a favorable influence on the paroxysms of uncomplicated whooping cough. This matter is now under investigation.

COMBINED FLUORESCENT AND MAZDA LIGHTING

To the Editor—We are having some difficulty in arranging the lighting facilities in an old school building. There has been considerable discussion regarding the use of fluorescent lights together with the ordinary bulbs in the same room. Do you know whether any actual research has been done to find out whether this combination of lights is detrimental or undesirable? H. B. Zemmer, M.D., Lapeer, Mich.

ANSWER—There is no harm in combining fluorescent lights with ordinary Mazda lights in the same room. The fluorescent lights are far more economical in consumption of electricity but more expensive for installation. It would be better to use the ordinary fluorescent, not the daylight, as that blends better with the Mazda and has the further advantage of being

more economical and more agreeable to the eyes. A further advantage of the fluorescent lights is that they are less intense. The light is spread over a larger surface and therefore is better for the eyes than the concentrated incandescent lights.

Painting the ceiling and upper part of the walls a light color is a great help.

MORPHINE AND LABOR

To the Editor—What is the present status of the use of morphine in the conduct of labor in the primipara? How much and how often can the drug be repeated with safety to both mother and child?

M.D., New York

ANSWER—Morphine is believed by many to be of distinct value as an analgesic during the first stage of labor and is considered safe for mother and baby when properly used. The most usable average dose is 1/6 grain (0.01 Gm). The drug should never be used until labor is rhythmic and well established. It should not be used near the end of the first nor ever in the second stage, because of possible harmful effects on the baby. In probably the great majority of labors the drug should be given but once in the course of a single labor. In certain long first stage labors with posterior positions of the occiput and breech presentations in primiparous women a second dose of the drug may be indicated. Notwithstanding present day methods of pain relief during labor, morphine may be considered a valuable and safe drug if conservatively used.

INHALATION OF COFFEE DUST

To the Editor—Would you be so kind as to discuss the possible harmful effects of the continued inhalation of powdered coffee that one might encounter in its manufacture?

Daniel G. Melvin, M.D., Greystone Park, N. J.

ANSWER—Experience on dusts of organic material in general indicates that these substances do not produce fibrosis. If any changes occur they are most commonly manifested as bronchitis or perhaps protein sensitization in susceptible individuals. Reports on the effects of coffee dust are lacking. Before assuming that exposure to this dust was exercising any influence on operatives, it would be well to make determinations on the number and size of the particles suspended in the air at the breathing level.

COLOSTOMY

To the Editor—What is the longest interval known to have elapsed between resection of adenocarcinoma of the hepatic flexure (first stage Mikulicz) and surgical restoration of the intestinal canal by closure of the colostomy? Is there any danger of the colon (transverse, descending, sigmoid and rectum) becoming atrophied because of its being excluded for a period of five or six years?

M.D., New York

ANSWER—Information on the longest interval between the first stage Mikulicz resection of the hepatic flexure and surgical restoration of the intestinal canal by closure of a colostomy is not readily available. There is probably no danger of the colon becoming atrophied to the point where closure cannot be made even after a period of five or six years.

UNUSUAL REACTION TO SHORT WAVE EXPOSURE

To the Editor—Regarding the query entitled "Unusual Reaction to Short Wave Exposure" (*The Journal*, Aug. 1, 1942, p. 1154), while I was treating a woman aged 27 for arthritic pains she occasionally became very anxious. She also complained of nausea and was afraid she would faint. As soon as the exposure was over (a 10 meter wavelength machine was used) she would feel better.

A. R. Aurelio, M.D., Brooklyn

To the Editor—In the answer to a query about an unusual reaction to short wave exposure (*The Journal*, Aug. 1, 1942, p. 1154), it is stated that similar reactions have not been reported so far. Nevertheless it seems that they are not unusual at all. My attention was attracted to this subject by several radio operators serving on ocean liners. They complained that the transmission of messages by ultra short waves was followed by a feeling of drunkenness, disorientation and exceptional nervousness while the same transmission under the same conditions but by medium waves did not produce any disturbance. One of these men had to walk on the ship deck for about two hours after his night service ended at midnight but this occurred only after transmitting by short waves. After ten to fifteen minutes of intense short (4 meters) wave diathermy of the neck or shoulders, I occasionally observed vertigo and a feeling of drunkenness of short duration. One patient almost fell from his chair when the current was turned off. Years ago I read that carrier pigeons, if released in the vicinity of a short wave transmitter, circle around and start in the right direction only when the transmission is over. It seems that these manifestations have something in common which would be worth while investigating.

ORTHOPEDIC SURGERY BETWEEN TWO WARS

CHAIRMAN'S ADDRESS

AMES A. DICKSON, M.D.
CLEVELAND

At a time when human energy and resources are being consumed on a scale never before imagined in the frenzied production of instruments of destruction, carnage and chaos, it is easy to agree with the cynics and pessimists who contend that there is no real progress in the world and that what we call civilization is completely doomed. But if we ponder more carefully the things we know best and the changes that have been wrought in our thinking as well as the environment in which we live, we know that this is not true. Change is eternal, the law of life, and those changes that endure are always for the better. Sometimes progress is so gradual that we are not aware of it, sometimes it is hastened by spectacular and stimulating events.

It is well, especially when immediate happenings are conducive of despair, to stop and give our attention to the changes for the better, the evidences of progress, in whatever is most familiar to us, thus to gain assurance and faith that still greater improvement will be forthcoming in the future. With all the deplorable devastation of a world war, the resourcefulness and enterprise of human beings are then stimulated to their highest peak of efficiency and result in advances, particularly in scientific fields, that might not be produced in decades of peacetime effort paced at a slower tempo. As some one has said, "War is an evil thing but has done good like a hormone, in activating the whole chemistry of the nation."

In no field of human activity is this more true than in medicine. A number of years ago my colleague Dr. William Lower summed up the medical experiences of the last war as follows:

Those lofty abstractions, Peace and Democracy, the stakes for which we gambled with so much money and so many lives are not within reach of mortal men, but we brought home a consolation prize of medical and surgical experience that has brought increased physical comfort and security to patients everywhere. Our experiences during the war have directly or indirectly influenced not only the practices in modern medicine but also its organization and professional personnel. We have reaped the advantages of the unparalleled opportunity accorded the officers of the medical units to observe large numbers of patients under the most trying of environments and to appreciate to the full the significance of such factors

as emotion, fatigue, exhaustion, shock, exposure, temperature and anesthesia. Surgical skill and judgment were tested under unprecedented circumstances. We learned the physical and economic significance of minor ailments, neuroses, injuries and operations. And we were taught, above all, the great value of team work and efficient organization. These things constitute the beneficent effects of war.

Our own specialty of orthopedic surgery received its impetus from the last war, and now, when we are embroiled in another conflict, seems an appropriate time to contrast some of the practices then and now and thus to realize the extent of progress that we, or many of us, have witnessed in our own lifetimes. We are aware, of course, that we modify our methods now and then, but in the daily routine of rounds and operations we scarcely realize the extent of the change or give it proper evaluation.

The experiences of caring for the casualties of the present fighting, which present many problems different from those in the first world war, probably will yield a comparable stimulus to orthopedic practices and will usher in a new period of development in our specialty. Hence the period from the beginning of the last war to the present one represents the first epoch in the history of orthopedic surgery as a recognized specialty of medicine.

The Orthopaedic Association and also the Orthopedic Section of the American Medical Association were in existence in the United States before the last war, but there was no comparable organization in Great Britain, and Robert Jones and his associates were virtually the only orthopedic surgeons in England who were widely known. The orthopedists had been looked on with disdain by other members of the medical profession here and were called the "strap and buckle" surgeons while Sir Robert had practically no status at all among certain of his confreres in England. He was derisively called a "bonesetter" despite his great surgical skill and the outstanding results he had achieved in caring for the cripples of Liverpool.

It is difficult to realize that such an attitude could have existed so recently toward the practice of orthopedics. It is hard to tell how long it might have persisted if it had not been for the war. Under serious opposition Robert Jones was entrusted with the establishment of the first military orthopedic service in any country, having two hundred beds at Alder Hey in Liverpool. The results were so striking that within a short period, thirty-three thousand beds were equipped and staffed with trained English and American orthopedic surgeons. As Lord Moynihan stated in the Robert Jones Birthday Volume:

A few months experience [of the war] showed that a very large proportion of surgical work would fall within the province of orthopedics. At the head of the orthopedic department at

the War Office Robert Jones found his destined place. He became the guide, the counselor, the example to a large band of workers, who quickly assimilated his teaching and were able to practice it on a scale hitherto unimaginable. The genius of Owen Thomas, the skill of Robert Jones, found their highest expression in service to our wounded. The methods of these two previously little known, and rarely practiced, now became the heritage and enjoyment of all who cared to seek acquaintance with them.

According to Goldthwait, 65 per cent of the casualties in the last war were orthopedic cases, and by the time of the armistice 569 officers had served with the Orthopedic Division of the American Expeditionary Forces. This group worked in the closest cooperation with Sir Robert Jones and the British group in efforts at standardizing procedures and equipment, and these experiences contributed later to maintenance of certain standards in orthopedic practice on both sides of the Atlantic Ocean.

Having had such a stimulus in the first world war the specialty of orthopedic surgery has thrived greatly until now we have more than seven hundred certified specialists. The spirit of Sir Robert still lives in the hearts and minds of those who came within the glow of his presence and learned humbly to love him, and his disciples have perpetuated and multiplied his gifts to humanity.

In a limited time it will be impossible to furnish any kind of comprehensive review of the many individual contributions to orthopedic practice which have developed in this period between the great wars. I choose rather with a deliberate attempt to stand off at an objective distance and to gain some perspective on modern developments, and thus, in the light of general principles which endure throughout the changing fashions of practice, to try to interpret general trends particularly in certain problems of greatest practical interest. When one strives for such a view, it becomes obvious that many controversial questions resolve themselves into a secondary place and that rivalries among protagonists of different techniques become relatively insignificant, since often these rivals are proceeding from the same principle and striving toward the same result.

This brings to mind Herbert Spencer's classic comments on scientific research which seem worth repeating at this time:

The efforts of numerous independent seekers carrying out their researches in different directions constitute a better agency for finding the true method than any that could be devised. Each of them struck by some new thought which probably contains more or less of basis in facts—each of them zealous on behalf of his plan, fertile in expedients to test its correctness and untiring in his efforts to make known its success—each of them merciless in his criticism of the rest—there cannot fail by composition of forces, to be a gradual approximation of all toward the right course. Whatever portion of the method any one of them has discovered must by the constant exhibition of its results, force itself into adoption, whatever wrong practices he has joined with it must, by repeated experiment and failure be exploded. And, by this aggregation of truths and elimination of errors, there must eventually be developed a correct and complete body of doctrine. Of the three phases through which human opinion passes—the unanimity of the ignorant, the disagreement of the inquiring and the unanimity of the wise—it is manifest that the second is the parent of the third.

And so it seems to me that many of the problems of orthopedic surgery are at present in the stage of apparent disagreement because of the search for true knowledge which is a wholesome sign, and the final agreement is not so far off as we may think.

COMPOUND FRACTURE

One of the most challenging problems to be faced by the orthopedic surgeon, even in peacetime is that of compound fracture and its complicating osteomyelitis. In war, with the great number of casualties of this type the interest in these cases increases. There is ample evidence in the current literature that much thoughtful attention is being accorded to these problems, and there are numerous techniques and agents for dealing with them which were not available to us in the first world war. The validity of these new methods will be judged finally on the results they achieve and these are dependent, in turn, on their adherence to the cardinal principles which is to say, on nature's laws.

Although our great surgical teachers have constantly reiterated that the aim of all good treatment is to aid the healing process of nature this cannot be repeated too often in view of the evidence that so many practitioners in their zeal for one method or another, or in exercising their own surgical virtuosity lose sight of this fact. The crux of the problem in compound fractures as well as simple fractures for that matter is rest and immobilization, and in compound fractures the picture is complicated by the presence of infection. No one has stated the matter more clearly than John Hunter, for he said:

The only peculiarity in compound fracture by which it differs from other lacerated wounds is the breach of continuity of the bone which admits of motion in the part where none was intended. This singularity it is which requires a peculiarity in the treatment as this motion and the operations of nature are in contradiction to each other. A variety of inventions have been employed to prevent this motion but the dressing of the wound every day counteracts the effect of every invention that has been thought of, and it is perhaps impossible to dress the sore without motion.

That is the problem which has faced us in the treatment of compound fracture and too often in the past emphasis on some detail of method has obscured the main issue. The controversy regarding sepsis versus antisepsis to which the surgeons of the last generation gave so much attention, is a case in point. Up to and during the first world war the emphasis was placed on a search for the ideal antiseptic, that is an antiseptic that might inhibit germ growth without damaging the tissues. The Carrel-Dakin method was hailed by many as the answer to all these searches. There was great enthusiasm for attempts to sterilize the wound with constant irrigations of the solution, but there was still so much disturbance of parts so much damage to the wound surface and so many accidental secondary infections that the results were disappointing. Much of the difficulty arose through concentration on the antiseptic treatment of the infection to the exclusion of the still more important factor of rest.

The futilities of some of these practices and controversies of the past we can all comprehend in the light of present experience. It may not be quite so easy to see that our own controversies, which hinge on such things as the relative value of this or that metal used in fixation of one technique of immobilization as

opposed to another, of one sulfonamide drug or another, of whether sulfonamide drugs should be given by mouth or packed into the wound and significantly enough persistent overtones of asepsis versus antiseptics, may be based on similar misconceptions and similar oversight of fundamental principles.

This is not to minimize the importance of all these developments. I believe they are extremely significant and that the individuals who have promulgated them in their persistent search for truth and knowledge deserve the highest praise. To appreciate them fully however, we must examine them in their relation to fundamental laws rather than in their relation to one another. To do this is encouraging for then comes the realization that modern methods however they vary in technical detail exhibit an awareness of the natural laws and a comprehensive understanding of the ends to be achieved in therapy.

An outstanding example of a thorough study and application of fundamental principles is represented by the work of Orr. His insistence on rest and immobilization with emphasis on asepsis, rather than antiseptics is responsible for the technic of treating compound fractures and osteomyelitis which has already had a major test in the present war first in Spain and later in Britain. Orr has emphasized that immediate reduction of the fracture and the adjacent soft parts and adequate immobilization of all parts in correct position are the primary essentials. With the parts in correct position and at rest, the operation of debridement and alignment of fracture may be carried through with a minimum of further damage. Thorough drainage is established and petrolatum dressings are packed into the open wound and then the immobilizing device which is to carry the patient through to recovery is applied. No postoperative dressings are done in the usual sense. If immobilizing devices become inefficient if discharge is profuse or if odor becomes unendurable dressings are changed usually in the operating room without disturbance of the part and with a minimum of damage to the wounded surface.

With the use of this method in combination with skeletal fixation, Trueta reported but six deaths in 1,073 cases of gunshot fracture treated during the Spanish Civil War. Wilson, in describing the results of Rodger-Anderson fixation and the closed plaster method at the American Hospital in Britain has pointed out that the comfort of the patients was an impressive feature. The only discomfort was from the odor, and this was more distressing to the doctors and nurses than to the patients.

Many of us have had sufficient experience with this method, or some modification of it, to be struck by the contrast between it and the cumbersome Carrel-Dakin technic. I can recall during the last war the tremendous labors in caring for patients with compound fractures, the formidable array of tubes and dressings, the emergency calls at all times of the day or night when something went amiss and the terrible suffering endured by the patients in the process. When one looks back and contrasts those experiences with the results of modern methods, one realizes that great progress has been made, because the patients are more comfortable, the course of recovery is more rapid and not only are the results better in respect to alignment of fractures and more rapid union but also infection is controlled and the wounds heal more rapidly.

In discussing the treatment Wilson has said

What is the secret of the Orr-Trueta treatment? It can only lie in the thoroughness of applying that great surgical principle of rest, which is so frequently disregarded in other methods of wound treatment. Rest favors the walling off of infection and the local defensive and reparative forces. The smooth and uniform compression of the extremity by the plaster is also important in preventing the development of edema in the region of the wound and maintains a better circulation in the extremity. Finally the sealing off of the wound in plaster of paris and the infrequent dressings prevent or reduce the cross contamination of wounds which recent bacteriologic studies show inevitably occurs when dressings are changed frequently even with the observation of the most careful aseptic technic.

The advocates of bismuth iodoform paraffin paste so-called bipp, which was introduced during the last war have pointed out the similarities between this method and the Orr treatment and have shown considerable concern over questions of priority. Those who have used bipp extensively are enthusiastic about it and it does indeed utilize essentially the same principles as the closed plaster method, although its development followed a different approach. Bipp was introduced as the result of constant search for a better antiseptic and the claim is made that it furnishes a constant supply of nascent iodine to the wound and thus obviates the necessity for constant dressings. Hence the desired result rest, is achieved and the satisfactory results reported by its users show that this has been an important contribution in offering additional proof that the details of method and the agents employed are secondary to the primary principles on which the results depend.

Modern methods of treating compound fractures have been greatly advanced by improved methods of skeletal fixation and also by the use of new metals for internal fixation of the bone fragments. These devices have been combined with the closed plaster method and with the use of sulfonamide drugs, with variations in technical details and each is important in that it contributes to rest, immobilization and control of infection. This is not the place to go into detail regarding the various methods of skeletal fixation or internal fixation. There have been controversies as to the relative merits of each. As I see it each has its own value in contributing to the better care of compound fractures, and the choice of the particular technic is governed by the findings in the individual case as well as by the experience and skill of the individual operator in one or another method, which naturally governs his preference. When internal fixation can be applied it is a valuable and satisfactory method, but in many war casualties this is not practicable and external fixation must be used.

In the problem of internal fixation Venable and Stuck have made a great contribution in their studies on the use of vitallium, an alloy of chromium cobalt and molybdenum. They have shown by physiologic experiments that this metal is inert to the action of tissue fluids, and hence many applications can be made that are not possible with other types of metal. There have also been significant advances in the development of new types of steel for this purpose.

It cannot be repeated too often that the principles of importance in the treatment of compound fractures are rest, immobilization and control of infection. Let us continue to improve the metals and apparatus used and to invent additional gadgets if they serve a useful pur-

pose, and let us investigate the relative merits of the new drugs being developed so rapidly in the field of chemotherapy, and let us take advantage of all the advances that are being made in other fields of medicine and surgery. But let us do so without slavish adherence to the details of one technic or another, but with understanding of its principles and interpretation of them in the light of fundamental laws.

NEW METHODS

The importance to orthopedics of developments in other fields of medicine and also in the basic sciences of physics and chemistry should not be overlooked. All knowledge is of one piece, and progress made in one segment has its effect in many other fields. The outstanding recent example of this is the development of the sulfonamide preparations and their constantly expanding uses affecting all types of cases. Their contribution in the treatment of compound fractures has been amply demonstrated, both when administered by mouth and when applied to the wound. As the work of Caldwell has shown, the time factor, that is, how soon the drug is implanted, is of paramount importance in control of the infection. When these drugs are used, the danger of gas bacillus infection which was such a horror in the last war is reduced to the point where it is practically negligible. Although much is still to be learned about their exact mode of action, it seems assured that their outstanding performance is due to a local bacteriostatic effect.

Methods of aiding the natural process of repair and healing, such as transfusions and nutritional factors, have been most important in treatment of compound fractures as well as other orthopedic conditions. If the patient is fortified by vitamins and transfusions and never has to suffer the debilitating and exhausting effects of serious infection, his progress is more rapid and his convalescence shortened. The control of shock by the use of transfusions removes many of the hazards of surgery and makes possible more extensive and radical procedures in many instances. The important studies made by the biochemists in devising methods for the preparation and storage of plasma have constituted a real contribution to surgery and orthopedics.

Advances in roentgenology have also contributed to the better treatment of fractures, by more accurate visualization of the injury to the bone, making possible a thorough check on the proper alignment of fragments. Physical therapy methods have undergone much refinement and study during the past decade and have been valuable in extending the applications of rest, heat and various forms of radiation, and in contributing to the preservation and restoration of function.

I have devoted considerable time to discussing compound fractures, because attention is focused on this problem in time of war and because the advances that have been made illustrate so nicely the question of general principles. Many other problems in orthopedics might be similarly examined. One that comes to mind immediately is the interest centering on the Kenny treatment of poliomyelitis, which is forcing reexamination of previous concepts, resulting in new study of the pathologic processes involved and hence of the type of treatment desirable in the early stages of the disease.

The list of new methods, introduced since the last war, which represent great progress in the treatment of

various conditions is long, far too long to be discussed here. But I cannot refrain from mentioning a few outstanding examples. The methods of stabilization of the paralytic foot introduced by Dunn in England and by Hoke in this country by fusion of the bones, rather than by tendon transplantation, have marked a great advance in the treatment of infantile paralysis. The work of Hibbs, wherein the natural process of fusion of the diseased joint in tuberculosis is aided by extra-articular grafts, and the demonstration by Rollier of the great importance of sunlight in these cases, have revolutionized the care of tuberculous patients. The internal fixation of fractures emphasized by Sherman, Murray and Smith-Petersen has been a splendid contribution. With the Smith-Petersen method the treatment of a fractured hip has become a relatively simple procedure in which good results can be confidently expected. Arthroplasty operations have been greatly improved on knees and elbows by the work of Campbell and on the hip by the use of the vitallium cup, as advocated by Smith-Petersen. Finally, reference should be made to the outstanding work of Bonnell in the treatment of tendon injuries by removable wire sutures. These are only a few of the significant improvements in methods that have been developed in orthopedic surgery since the first world war.

Thus, when we examine the advances in orthopedic practices in the light of general principles, we have reason to feel that we have been moving steadily forward and that much satisfactory progress has been made. The members of our group have been quick to realize the value to our work of new developments in other fields and to devise specialized applications of them. And they have been striving unceasingly to improve the methods, apparatus and operations that belong peculiarly to orthopedic surgery.

When these new technics are observed with sufficient perspective and objectivity, it is obvious that they all tend in the direction of adherence to fundamental precepts. Some of us, in our enthusiasm for one method or agent at times fail to see the merit in some other technic which may be regarded as competitive and engage in controversy which gives more attention to details than to principle. In the long run, however, these differences will prove insignificant, for even now it is evident that they are more apparent than real. Such differences of opinion are inevitable and essential to the progress of investigation and inquiry, but they are shadows which disappear in the clear light of truth and certain knowledge.

THE FUTURE

The specialty of orthopedic surgery, then, may be said to have had its origin in the throes of a great war and, through the impetus of the necessity thrust on it at that time, to have made great strides which have constantly been developed in the intervening years. Thus we are able to face the problems presented by a new conflict with many new tools and methods, which will no doubt be developed with great rapidity during this war. A considered view of the past era gives us much hope for the future, and we can look ahead with calm assurance that progress and betterment are inevitable. "Tribulation worketh patience and patience, experience, and experience, hope."

PAIN AND DISABILITY OF THE
SHOULDER AND ARMTREATMENT BY INTRAMUSCULAR INFILTRATION
WITH PROCAINE HYDROCHLORIDEJANET TRAVELL, MD
SEYMOUR RINZLER, MD
AND
MYRON HERMAN, MD
NEW YORK

When a patient presents himself with the common complaint of pain in the shoulder region and arm with or without limitation of motion and unrelated to severe trauma, the physician usually thinks of the joints, bursae, tendons or nerves rather than of the shoulder girdle muscles as the primary source of pain. Thus the customary diagnosis in this type of patient is either arthritis, subacromial bursitis, brachial neuritis or radiculitis. The well known chronicity of these symptoms and the variety of therapeutic procedures employed suggest either that the customary methods of treatment are unsatisfactory or that the underlying cause is often overlooked. It is our purpose in this report to discuss the diagnosis of a type of pain in the shoulder and arm which has its origin in the muscles of the back or shoulder girdle and to present the results of an effective method of therapy, namely intramuscular infiltration with procaine hydrochloride.

The rationale for this type of therapy is based on several observations. First, it has long been recognized that many instances of "painful shoulder syndrome" present tender areas in the muscles around the shoulder ("periartrosis"). Second, it has been demonstrated that tender areas in muscles may cause pain not only locally but also referred to other somatic structures. The characteristics of referred somatic pain have been studied experimentally by Kellgren and Lewis.¹ In this connection the term "trigger zone" was used by Edeiken and Wolferth,² since in 2 instances of "painful shoulder syndrome" pressure on a tender area in the supra-scapular region increased the radiation of pain in the arm. Steindler and Luck³ demonstrated the role of "trigger points" in the muscles of the lower part of the back as sources of pain referred to the leg; injection of procaine into these tender points abolished not only local tenderness but also referred pain. The third observation that recently encouraged the therapeutic application of procaine by the intramuscular route was an empirical one. Steindler⁴ found that this technic was valuable not only in locating the source of pain but also as a therapeutic procedure in "sciatica."

The literature at present indicates greater enthusiasm for this technic in the treatment of pain in the lower than in the upper extremity.⁵ Following his earlier observations on the injection of procaine into "trigger

points" in the lower back muscles, Steindler fails to mention this technic in connection with the treatment of the "painful shoulder syndrome."⁶ Although reports of isolated cases have appeared which advocate intramuscular infiltration with procaine for pain and disability of the shoulder and arm,⁷ no systematic investigation of this technic in this condition is available. It seemed to us therefore, that the possibilities of this method of therapy had not been sufficiently explored in relation to the "painful shoulder syndrome."

DIAGNOSIS

Description of Cases—A group of cases coming to our attention because of the outstanding complaint of persistent pain in the shoulder region showed on examination the presence of tender points in various muscles of the shoulder girdle. Fifty-eight cases were selected for treatment and form the basis of the present report. The patients were, with a few exceptions, ambulatory. About two fifths had hypertensive and arteriosclerotic cardiovascular disease, one fifth had pulmonary tuberculosis and two fifths had general medical complaints. The medical group was comprised of 5 patients with chronic sinusitis, 2 with hypothyroidism, 1 with Paget's disease, 1 with wet beriberi and 16 in whom the shoulder syndrome was the only apparent abnormality. There were 37 males and 21 females. Two patients were colored, 1 was Chinese. The ages ranged from 29 to 78 years, the average was 55 years. About one third of the patients had both shoulders involved, the right shoulder was the one involved in 51 per cent and the left in 40 per cent of the 76 affected shoulders. In approximately one third of the shoulders, pain had been present for less than two months before treatment, in one third for from two to eleven months and in one third for a year or longer. A variety of occupations both sedentary and extremely active, was represented and, with perhaps a few exceptions, no relation to the shoulder pain was apparent, one third of the patients were unemployed. The onset was gradual in most instances. The precipitating factors appeared to be manifold and included physical fatigue, chilling infection, trauma, confinement to bed or a period of relative muscular inactivity, and poor posture, especially a tendency to become "round shouldered."

Somatic pain elsewhere than in the shoulder and arm was a complaint in 38 per cent of the cases. Acute pain arising in trigger points in muscles in these other regions usually was dramatically relieved by intramuscular infiltration with procaine, and an enthusiasm for the general application of this type of therapy for pain of muscular origin, expressed especially in the British literature, seems to be entirely warranted.⁸

The distribution of pain in the upper extremity varied. It was usually most intense over the front or back of the deltoid region, was occasionally felt in the scapular region and frequently radiated to the forearm and hand in which paresthesias were sometimes present. Rest pain was present in 72 per cent of the cases. Pain was always elicited or increased by active motion and was associated in about three fourths of the cases with limitation of active motion at the shoulder joint. The

most common type of limitation was difficulty in placing the hand behind the back, this was noted in all but 1 instance. The distribution of cases according to the severity of pain and limitation is shown in table 3. There were no neurologic changes.

Trigger Points and Pain Radiation—All the cases presented one or more "trigger points"⁹ or "myalgic spots"¹⁰. Such an area is more resistant than the sur-

rounding muscle, it often extends to the entire triceps region, occasionally to the ulnar border of the forearm, the palm and fourth and fifth fingers of the hand, and the pectoral region, and less frequently to the spinous processes of the upper two or three thoracic vertebrae. It is possible that the variations in pain radiation from this muscle depend on variations in its anatomic structure, one or more of the slips are frequently absent.¹¹ Muscles in the reference zone which have the same segmental innervation as the trigger point in the upper part of the serratus posterior superior, namely the eighth cervical and first thoracic¹² include the pectoralis minor and major, triceps brachii extensor and flexor carpi ulnaris, flexors of the digits, muscles of the little finger and deep muscles of the hand.

Next in frequency as a source of referred pain was the infraspinatus (fig 1). A tender point was found in this muscle in half of the affected shoulders. The radiation of pain from this muscle (fig 2B) is quite constant; it is most intense over the front of the shoulder and the long head of the biceps and may extend down over the entire biceps to the brachioradialis muscle. These muscles like the infraspinatus, are innervated by the fifth and sixth cervical segments. The reference of pain from the infraspinatus to the "shoulder tip" has also been noted by Kellgren.¹

A number of less frequent but clear cut reference patterns were observed from trigger points in other muscles of the shoulder girdle. In general the radiation of pain was in agreement with the somatic reference zones which Kellgren and Lewis have mapped out for single spinal segments.¹

Differential Diagnosis—The minimal criteria for the diagnosis of shoulder and arm pain due to "idiopathic myalgia" on the basis of which infiltration with procaine may be undertaken are (1) increased pain on active motion elicited either by a quick or sustained effort and (2) tender points in the muscles of the back or shoulder girdle. Reproduction of the spontaneous pain pattern by pressure on the tender point and limitation of motion are valuable signs when present but are not essential to the diagnosis. Confirmation of the pre-

Fig 1—The left side shows the shoulder girdle muscle with the trapezius and deltoid muscles removed. The right side shows the overlying of the serratus posterior superior muscle by the scapula in ordinary posture.

rounding muscle and is excruciatingly tender on strong pressure. It is usually not identical with the site of spontaneous pain. Pressure on the area may increase or elicit pain in the reference zone. Either active contraction or passive stretching of the muscle in which the trigger point is located may induce referred pain. Not only pain but also tenderness and weakness of the muscles in the reference zone may be pronounced. This is in line with the demonstration¹⁰ that stimuli arising in a muscle or ligament can provoke not only pain but also tonic contraction of muscles at a distance having the appropriate segmental distribution, hence the phenomena customarily described as "referred" may actually be the result of reflex changes in the so-called reference zone.

Trigger points were found in various muscles in the shoulder girdle or back, and it seems likely that any muscle innervated by the spinal segments from the fifth cervical to the first thoracic may cause radiation of pain to the upper extremity. The vast majority of cases presented between two and four such trigger points.

The muscle that most often caused pain in the shoulder region and arm was the serratus posterior superior. A tender point in this muscle was present in 57 of the 58 cases, or in all but 1 of the 76 shoulders affected. In 8 cases it was the only primary source of pain. The trigger point was usually located in the upper lateral portion of the muscle and was partially covered by the scapula (fig 1). In order to expose it for palpation and injection, the scapula was retracted and its upper part rotated laterally by placing the hand in the opposite axilla, depressing the shoulder and flexing the spine. The radiation of pain from this muscle is shown in figure 2A. The referred pain is most intense over the long head of the triceps brachii at the posterior border of

Fig 2—A radiation of pain from the serratus posterior superior muscle. B radiation of pain from the infraspinatus muscle.

sumptive diagnosis is usually secured by the therapeutic test of infiltration of the myalgic points with procaine.

The conditions from which this syndrome should be differentiated include

1. Abnormalities of the bones and joints such as fractures, dislocations, cervical rib, and arthritis. These are readily demonstrated by roentgen examination.

2 Subacromial bursitis. A true acute bursitis may be recognized by the usual signs of inflammation, especially local swelling.¹⁴ The mere presence of a calcific deposit in the region of the subacromial bursa is not a sufficient basis for the conclusion that the symptoms are caused by a chronic bursitis. Such deposits may exist for years without pain.¹⁵ In our series calcification in the shoulder region was noted in 3 of 27 patients having roentgen studies and did not influence the results of therapy (fig 3). The frequent reference of pain to the deltoid region from the muscles of the shoulder girdle and the occasional presence of a primary source of pain in the deltoid muscle itself explain the frequency with which a diagnosis of chronic bursitis is pinned on the patient with shoulder pain and disability due to foci in the muscles.

3 Scalenus anticus syndrome. This is characterized by pain in the upper extremity and neck, signs of venous obstruction, vasomotor changes and, if severe, evidences of arterial insufficiency and damage to the motor and sensory nerves.¹⁶ It is apparent from certain cases in our series that pain due to involvement of the scaleni can result not only from neurocirculatory compression but also from trigger points located in the scaleni muscles themselves, the referred pain extends to the biceps, radial border of the forearm and proximal interphalangeal joints and is associated with an inability to close the fingers. Evidence that in these cases the pain is referred is afforded, first, by the lack of objective signs of compression and second, by the correspondence of the segmental radiation of pain with the innervation of the scalenus anticus muscle (the fifth to the seventh cervical segments). When frank signs of brachial plexus compression are manifest, pain is present chiefly in the ulnar distribution (eighth cervical and first thoracic), because of the greater impingement of the scalenus anticus muscle on the lower rather than on the upper fibers of the brachial plexus.¹⁷

4 Neurogenic disorders, including compression of the brachial plexus from any cause, brachial neuritis, radiculitis and spinal involvement of the spinal cord. These causes of pain and disability of the upper extremity may usually be discovered by a complete neurologic examination. In our series, the diagnosis of shoulder pain of muscular origin was overlooked in 1 case in which there were residual signs of an old hemiplegia on the affected side, prompt remission of pain and restoration of motion followed infiltration of trigger points in the shoulder muscles with procaine.

5 Coronary artery pain. The frequent association of acute coronary thrombosis and angina pectoris with intractable pain in the arm and limitation of motion at the shoulder has been noted.¹⁸ Thirteen of our patients had effort angina and/or myocardial infarction. Although the similarity in the radiation of pain from trigger points in the serratus posterior superior (fig 2A) to that of effort angina is obvious, patients had

no difficulty in distinguishing between pain of somatic and of cardiac origin. The differentiation depends not on the distribution of pain but on the presence either of constant rest pain, which is aggravated by some motion of the arm or, if rest pain is absent, of pain on motion or limitation of motion at the shoulder joint and on the finding of trigger points in the scapular region.

Fig 3—A calcific deposit in the region of the right subacromial bursa of a stenographer aged 28 who had moderately severe (2+) pain in the right shoulder joint and deltoid muscle of three weeks duration. The pain was completely relieved by a single treatment in which 12 cc. of 1 per cent procaine hydrochloride was injected into tender points in the infraspinatus, serratus posterior superior and levator scapulae muscles.

6 Vascular disorders of the upper extremity such as embolism and thrombosis. The picture is generally so striking that it rarely presents a diagnostic problem.

TECHNIC

Material—A 1 per cent aqueous solution of procaine hydrochloride without epinephrine was used in most instances. In 2 cases treatment with a 0.7 per cent solution was successful. In a few isolated observations a 0.5 per cent solution seemed not to be as effective as higher concentrations. Control infiltration with isotonic solution of sodium chloride was ineffective.

Procedure—The maximum point of tenderness was located with precision. This was facilitated by putting the muscle "on the stretch" and by the use of strong pressure. The cooperation of the patient is essential in locating points of tenderness exactly. It has been recognized that "blind" injection in the hope of infiltrating a trigger point by chance is usually ineffective.¹⁹

After a small intradermal wheal had been made a sufficient amount of procaine solution was injected to abolish local tenderness. Usually 2 to 5 cc sufficed for a given site. If the first injection failed to secure the desired result, the area was reinjected at a different level.

Referred pain was often induced momentarily and was helpful in demonstrating the accuracy of injection. If the muscle was infiltrated slowly, little pain was produced. That the primary focus of pain had been reached was indicated by disappearance or diminution in rest pain or improvement in active motion within a few minutes after injection. Frequently an immediate sensation was felt in the arm described as heaviness, deep

seated numbness or coldness, which was especially noticeable after infiltration of the serratus posterior superior

If the patient's tolerance permitted, as many points as possible were injected at each visit in an attempt to render the patient entirely free from pain and limitation

Dosage—The amount injected at any one visit was usually between 10 and 20 cc of the 1 per cent solution. An initial test dose of 1 to 2 cc was given to patients not known to have received procaine previously. The maximum amount at any visit was 100 cc given over a period of two hours. It is stated that 50 cc of a 1 per cent solution represents a conservative amount to secure local anesthesia in operative procedures,²⁰ it should be noted that in this case much of the material is given subcutaneously. Owing to rapid absorption from the intramuscular route, the susceptibility of the patient to minor toxic effects usually limited the dose to not more than about 5 cc every five minutes.

Reactions—No serious procaine reactions were encountered in a total of two hundred and fifty-four visits, in spite of the fact that many of the patients had

Late reactions consisted only of pain or tenderness in the area infiltrated and increased pain in the reference zone. The severity and duration of these after-effects varied greatly and were not predictable.

Signs of sensory or motor nerve paralysis were not observed following injection of the shoulder girdle muscles. There was also no evidence of penetration into the pleural cavity.

Frequency of Injection—Owing to the facilities of the clinic it was usually possible to treat patients only at weekly intervals. To a few hospitalized patients, treatments were given more often, even daily. The optimum interval for repeated infiltration of a given site may differ in different cases, it probably ranges from about four to ten days.

Interim Treatment—As adjuncts to procaine infiltration, the medication included only the occasional use of analgesics, ascorbic acid 75 to 200 mg daily in 5 cases in which soreness after infiltration presented a problem and wheat germ 30 Gm daily in 8 cases in which generalized myalgia was present. It is our impression that ascorbic acid was of value in reducing local reactions, owing perhaps to the effects of this vitamin on the speed of tissue repair.²¹ Wheat germ given in this dose over long periods was in our opinion of no benefit.

Other therapeutic procedures were the application of local heat as desired (electric pad, hot water bottle) and the encouragement of active motion of the arm within the limits of pain. Passive motion was not used routinely because it seemed to increase pain.

RESULTS OF TREATMENT

Complete relief of both pain and limitation of motion was secured by this technique in 62 per cent of the cases, moderate to considerable improvement in 31 per cent and little or no relief in 7 per cent (table 1). The results are essentially the same for patients with cardiac or pulmonary disease and those without intrathoracic disease. The average period of observation of those patients who obtained complete relief ranged from one to sixteen months; the average was 5.4 months.

Complete relief of limitation of motion occurred somewhat earlier and in a slightly higher percentage of the affected shoulders than did complete remission of pain, namely in 70 and 62 per cent respectively. The average number of treatments which abolished limitation was 2.6, and that which abolished pain was 3.5. Complete relief of limitation was secured by one treatment in 36 per cent of the 50 shoulders presenting restricted motion, whereas complete relief of pain was obtained by one treatment in only 12 per cent of the 76 affected shoulders. Improvement in active motion was always attended by diminution of pain.

The average number of treatments per affected shoulder was 4.2 (table 2). As a rule, improvement was immediate and dramatic. Of the 72 painful shoulders in which complete or partial relief was obtained, definite diminution in pain occurred after the first treatment in 64 instances, after two treatments in 5 and after three treatments in 1 instance. This suggests that if definite improvement is not apparent after about three treatments, it is probably not worth while to continue this method of therapy.

The duration of the shoulder pain before treatment definitely influenced the results of treatment (table 2).

TABLE 1—Results of Treatment in Various Clinical Groups

Group	Total Cases	Average Age Years	Pain and Limitation of Motion		
			Limitation of Motion Cases	Complete Relief Cases	No Relief Cases
Cardiovascular	23	61 (41-78)	19 (83%)	14 (61%)	2 (9%)
Pulmonary	10	47 (33-63)	8 (80%)	5 (50%)	1 (10%)
Medical	25	52 (29-72)	15 (60%)	17 (68%)	1 (4%)
All types	58	55 (29-78)	42 (72%)	36 (62%)	4 (7%)

a low cardiac reserve. In cases presenting effort angina, the repeated injection of procaine was not associated with the appearance of coronary artery pain.

Immediate minor toxic effects were noted at some time in approximately 40 per cent of the cases. These effects were transient and usually lasted only ten to twenty minutes. They included dizziness, talkativeness, partial deafness, a sensation of constriction of the throat, and thirst. One patient, known to have asthma, had an attack of asthma which was readily controlled by epinephrine. The same type of reaction was generally observed at different times in the same patient. Dizziness was the most common one and, unless severe, was considered not as a contraindication to further injection of procaine but rather as an indication for lengthening the interval between doses. The speed of administration is an important factor in determining the toxicity of procaine because of its rapid destruction by the liver.²¹ At a fairly uniform rate of infiltration it was apparent that the individual susceptibility was more important than the total dose of procaine in determining the appearance of minor toxic effects. For those patients who never had a reaction at any visit the average maximum dose was 19.4 cc, and the range was 5 to 100 cc, for those who showed a reaction, the average was 28 cc, and the range, 5 to 60 cc.

Of 23 shoulders affected for less than two months, regardless of the severity, nearly all secured a perfect result, and in 9 instances only one treatment achieved this. In the groups affected for from two months to a year or for more than a year, a perfect result was achieved in only about half of the affected shoulders and in not a single instance did one treatment suffice to attain this. However, the degree and speed of recovery was about the same whether the duration before treatment was several months or a few years.

The relation of the severity of pain and limitation of motion to the results of treatment is shown in table 3. When the limitation was slight (1+) normal motion was nearly always restored, whereas when there was extensive limitation (2+ and 3+) this result was achieved in only about 60 per cent of the shoulders, this difference appeared in spite of the fact that the proportion of those having involvement for less than two months before treatment was lower for the mild than for the severe grades of limitation. The severity of the pain also appeared to be a factor in the outcome since a per-

portion to the severity of the pain, that is, pronounced restriction of motion was associated with pain only on motion and not at rest. Contrary to other observations²³ the relative degree of localization and of reference of pain did not depend on the depth of the primary source of pain beneath the body surface. These facts suggest that different pathologic processes may be represented in muscles which behave differently with respect to the degree of reference of pain and to the speed of response to this type of therapy.

The high degree of success which we have achieved by this method of treatment of the "painful shoulder syndrome" is probably attributable to (1) identification of new trigger points, (2) recognition of the specific referred pain patterns from different trigger points, (3) avoidance of infiltrating areas of referred pain and tenderness and (4) persistence in injecting all primary sources of pain. The trigger points in the serratus posterior superior and infraspinatus muscles which we have found to be the most frequent sources of shoulder and arm pain, are not indicated in the charts of "myal-

TABLE 2—Relation of Duration of Shoulder Pain Before Treatment to Results of Treatment

Duration Months	Total Shoulders Involved	Complete Relief of Pain			Improvement in Pain		No Relief of Pain	
		Number of Shoulders	Secured by One Treatment *	Average Number of Treatments	Number of Shoulders	Average Number of Treatments *	Number of Shoulders	Average Number of Treatments *
Less than 2	23	21 (91%)	9	2.8 (1-10)	2 (9%)	2.5 (1-4)	0 (0%)	
2-11	29	12 (41%)	0	4.2 (2-10)	16 (55%)	5.5 (1-18)	1 (4%)	3
12 or longer	24	13 (54%)	0	3.9 (2-7)	8 (33%)	6.6 (3-15)	3 (13%)	4 (3.3)
All periods	76	47 (62%)	9	3.5	25 (33%)	5.7	4 (5%)	3.8

* The term treatment is used to indicate a single visit at which one or more myalgic areas were injected.

fect result was obtained in 69 per cent of the shoulders exhibiting the lesser degrees of pain (1+ and 2+), as compared with 53 per cent of those exhibiting very severe (3+) pain, it should be noted that the proportion of those having involvement for less than two months was higher for the group with the poorer result.

Failure to secure relief occurred in 4 cases. In 1, the pain was of extremely long duration (thirty years), treatment was discontinued because of pronounced dizziness and increased pain after infiltration. In 1 case, failure was attributed to inaccessibility of trigger points located anterior to the scapula, and in 2 cases, possibly to an error in diagnosis, since roentgenograms showed extensive osteoarthritis of the spine, although inaccessibility of the points may have been a factor in these cases also.

One reason for the fact that about a third of the patients secured striking improvement but not a perfect result was inadequate treatment. Another was a tendency toward recurrence, which suggested that the factors which originally precipitated the symptoms were still in operation, such as occupational strain of the arm or the presence of the chest deformity of chronic emphysema. Another factor was the character of the pain. In a few cases, the tender points in the muscles gave rise to local rather than to referred pain, as shown by the fact that procaine abolished pain only at the site of injection and not at a distance. These cases were unusual in that the amount of limitation was out of pro-

portion to the severity of the pain and tenderness in myalgic states" at which local analgesic injections are given.²⁴

Assuming that a correct diagnosis of "idiopathic myalgia" has been made and that the primary sources of pain and their referred pain patterns are recognized there still remain certain limitations to this method. Difficulties may be encountered because of (1) low tolerance to procaine, (2) poor cooperation of the patient in locating the myalgic points owing to deafness, a language difficulty or temperament, (3) inaccessibility of the primary sources of pain, that is their location in the subscapularis or serratus anterior muscles in front of the scapula, (4) continuance in operation of the precipitating factors, (5) chronicity, (6) multiplicity of points and (7) a high degree of local rather than of referred pain.

MECHANISM OF PROCAINE ACTION

Since the nature of the myalgias is obscure, the mechanism by which procaine permanently relieves pain and restores motion is of necessity unknown. Although generalized or localized pain and tenderness in the muscles is most often designated as fibrositis, myositis or fibromyositis there is evidence that this condition may not be inflammatory in origin; the temperature, blood sedimentation rate and blood count are usually

23 Kellgren.¹

24 Steinbrocker's first reference. Gutstein Good.²

normal, and in some instances biopsies of the painful, indurated muscle areas have not revealed signs of inflammation²⁵ It is possible that the fibroblastic proliferation which has been observed in other cases is secondary to a functional disturbance and occurs only if the latter persists for a period of time The meager pathologic data relating to this condition have been recently reviewed²⁶

One theory as to the mechanism of the lasting therapeutic action of procaine is that the temporary abolition of pain permits an increased range of motion and a consequent breaking of adhesions and absorption of exudates¹⁰ This implies that the limitation of motion is due to a structural lesion and that permanent relief of pain is the result of the improvement in motion This mechanism would not apply to the relief obtained in those cases characterized by rest pain without restriction of motion

TABLE 3—Relation of Severity of Pain and of Limitation to Results of Treatment

Severity *	Pain			Limitation of Motion		
	Complete Relief			Complete Relief		
	Total Shoulders	Number of Shoulders	Duration Less Than 2 Months	Total Shoulders	Number of Shoulders	Duration Less Than 2 Months
1+	26	18 (69%)	6 (33%)	26	23 (88%)	6 (23%)
2+	16	11 (69%)	3 (27%)	19	11 (58%)	3 (27%)
3+	34	18 (53%)	10 (29%)	5	3 (60%)	3 (100%)
All degrees	76	47 (62%)	19 (40%)	50	35 (70%)	12 (24%)

* Pain 1+ pain only on motion
2+ moderate rest pain
3+ severe rest pain

Limitation (active motion) in any direction
1+ restriction less than 25 per cent of normal range
2+ restriction 25-75 per cent of normal range
3+ restriction greater than 75 per cent of normal range

Another theory, advanced by Leriche²⁷ is that a disturbance of the sympathetic nervous system causes localized vasoconstriction within the muscles which results in ischemic pain

A third and, it seems to us, the most plausible hypothesis is that the pain is the consequence of a sustained spasm of the skeletal rather than of the arterial musculature, which likewise results in ischemic pain According to this view, limitation of motion is primarily a reaction to pain rather than the result of a structural lesion If muscle spasm causes pain and pain reflexly produces muscle spasm a self-perpetuating, pain-producing cycle might be established under certain conditions which would explain both the chronicity of the symptoms and the mechanism of cure by procaine In this case procaine injected intramuscularly would break the vicious cycle by relaxing the localized muscle spasm, by virtue of its action in blocking afferent nerve impulses or by its curare-like action at the motor end-plates²⁸ That the former action alone is sufficient

to interrupt the cycle is suggested by the permanent relief of pain in the upper extremity, secured in some cases following brachial plexus block²⁹ or suprascapular nerve block³⁰ Failure of brachial plexus block in other cases might be explained by the fact that at this site of injection procaine does not block the intercostal and suprascapular nerves which supply the serratus posterior superior and infraspinatus muscles In the case of suprascapular nerve block, improvement would be anticipated only if the primary focus of pain were located in the suprascapular or infraspinatus muscles Another therapeutic procedure which is sometimes effective in the myalgias is strong sustained pressure applied directly on the tender point in the muscle which serves as the source of referred pain (Libman maneuver) The mechanism of action of this procedure has not been explained but may be analogous to that of procaine in interrupting tetanizing motor discharges, since it has been shown that 25 pounds pressure per square inch will block motor nerve fibers, the small sensory nerve fiber is more susceptible to the action of procaine than is the large motor fiber, whereas the reverse applies to the effect of pressure³¹ The relief of pain and limitation of motion by ethyl chloride applied to the skin over the tender muscles³² might be explained by a similar mechanism since local anesthesia of the skin produces relaxation of the skeletal muscles having the same segmental innervation presumably by altering the tonic impulses³³ It is noteworthy that all these varied procedures which relieve pain in the upper extremity have in common the effect of relaxing muscle

SUMMARY AND CONCLUSIONS

1 Treatment by intramuscular infiltration with procaine hydrochloride was carried out in 58 cases exhibiting pain in the shoulder region and arm These cases were characterized by tender points in the muscles of the back and shoulder girdle, by increased pain on active motion of the arm and in about three fourths of the 76 affected shoulders by limitation of active motion at the shoulder joint

2 Full restoration of motion and complete remission of pain were secured by this technic in 62 per cent of the patients, 31 per cent showed improvement, and no relief was observed in 7 per cent Complete relief of pain and disability was obtained in 91 per cent of those whose symptoms had been present for less than two months

3 The results of procaine infiltration were similar whether the "painful shoulder syndrome" occurred in patients with heart disease with pulmonary tuberculosis or without intrathoracic disease This suggests that this type of pain in the upper extremity is not dependent on visceral impulses

4 The therapeutic effect of procaine infiltration indicates that in these cases the pain in the shoulder and arm is the direct result of impulses arising in one or more foci in the muscles of the back or shoulder girdle The restriction of motion is primarily a reaction to pain The term "idiopathic myalgia" best describes the syndrome

TREATMENT OF CARCINOMA OF THE CERVIX WITH INTER- STITIAL RADIATION

ROSCOE W TEAHAN, MD MSc (SURG)
HOKE WAMMOCK, MD
AND
JAMES WEATHERMAN, MA
PHILADELPHIA

In 1898 Wertheim introduced the principle of extended radical abdominal hysterectomy for the treatment of carcinoma of the cervix but this procedure carried with it a high mortality. Good results were obtained only when the disease was discovered in an early stage. Soon after this, radiation was used by Curtis in 1902 and radium in 1906. The early results obtained from radiation alone were very poor owing at least in part to the failure to penetrate the tissues deeply. In fact the first favorable reports of the treatment of this disease with radiation came from the use of radium alone.

The method most frequently used in applying radium has been that in which it is placed in the uterine canal and in the vagina against the cervix. For the great majority of patients in whom one or both broad ligaments have become involved the central portion of the disease may be destroyed but actively growing cells at the periphery receive inadequate irradiation.

A strong difference of opinion exists concerning the frequency of involvement of the parametrial lymph nodes. Palpation alone cannot be depended on to detect small invaded nodes. Sandler,¹ extracting from the literature only cancers of earlier stage treated by surgery in which complete serial sections were made, reported involvement in 33 to 51 per cent of the patients studied. Taussig² states that he has found 15 to 25 per cent with involvement of the lymph nodes in stage 1, and up to 60 per cent in stage 4 cancers.

The problem is essentially one of delivering lethal amounts of radiation to the outermost parts of the diseased areas. Attempts to solve this have been made through the use of high voltage external x-radiation, the development of new types of intravaginal and intrauterine applicators, the use of interstitially placed radium, and a method that is a combination of the others.

With the advent of equipment capable of producing high voltage radiation, external irradiation was again tried and occasionally good results are obtained through its exclusive use. But it seems generally agreed that this method alone is unacceptable provided there seems to be any chance of curing the patient.

Stevenson was the first to report the successful use of interstitial radiation in carcinoma of the cervix. In 1919 Daels began to apply radium to the pelvis after exteriorizing the area by surgical operation. In 1922 Delporte and Cahen reported on the intra-abdominal application of radium. In the United States Ward was among the first to use radium interstitially in the cervix, and since then there have been many who have used some type of interstitially placed radiation, either radium element needles or radon, for the treatment of

this disease. Pitts and Waterman³ report good results by interstitially placed long needles containing small amounts of radium. While at first they opened the abdomen for such application, more recently it has been done entirely by the intravaginal approach. Gellhorn⁴ began to apply radium interstitially by the intra-abdominovaginal route in 1930. In 1934 and the years following Healy and his associates⁵ called attention to the inadequate amount of radiation reaching points several centimeters distant from the cervix. In 1938 Arneson⁶ described his method of applying radium interstitially in the treatment of carcinoma of the uterine cervix.

In January 1933 we began the treatment of carcinoma of the cervix by interstitial radiation applied with the abdomen opened. The method we are now using and are reporting is an elaboration of the technique previously described. Every patient with a condition as serious as carcinoma of the cervix should have treatment carefully outlined before any is undertaken. This calls for a rather complete physical examination and biopsy to the end that the extent of the disease will be known as accurately as possible. In most instances a cystoscopic examination is indicated—in some, a proctoscopic examination—and a lesser number require

Fig 1—Method of treatment. 1 Roentgen treatment precedes application of radium by four weeks. 2 Abdominal exploration and application of radium by the interstitial and intracavitary method.

Radium content Active length Filter	Radium Needles		Radium Tubes	
	1 mg 10 mm 0.5 mm of platinum	2 mg 21 mm 0.6 mm of platinum	13.33 mg 15 mm 1.0 mm of platinum	260 hours
Time	760 hours		260 hours	

other x-ray diagnostic studies. An initial blood count should be made and if any anemia is present this should be repeated a number of times during the course of the treatments. If after such procedures are carried out it is considered that the patient is in sufficiently good condition to warrant an attempt at cure, roentgen treatment is begun and the following factors are used: 200 kilovolts, 50 cm skin target distance, Thoraeus filter, half value layer, 1.7 mm copper filter, 200 roentgens is given daily to two ports anterior and three ports posterior each field being 10 by 15 cm anterior and posterior ports being alternated. This is continued until the skin shows definite irradiation effects. The anterior ports generally receive 2,000 to 2,400 roentgens and the posterior ports about 1,800 to 2,000 roentgens.

After the roentgen treatment has been completed four weeks is allowed to elapse before the radium is applied. The application is made under a general anesthetic, with the patient in the lithotomy position. The abdomen is then opened through a lower midline incision, and the abdominal contents are explored both

Fig 2—Anteroposterior view of pelvis showing position of radium tubes and needles

for the extent of the disease and for the presence of metastases. Very often adhesions will be found between the intestine and the pelvic structures that should be separated. Especial attention is paid to the iliac region,

Fig 3—Lateral view of patient shown in figure 2

and if any enlarged glands are felt they are removed. It has been our practice to remove both tubes and ovaries at this time. A bimanual examination is then made with the left hand grasping the uterine fundus while the fingers of the right hand are inserted into the vagina. In this way it is possible further to determine the extent of the involvement and plan the distribution

of the radium. The cervical os is gently dilated sufficiently to admit the intrauterine applicator, which is put in position after the radium element needles have been implanted.

Generally nine or ten 1 mg. radium element needles are placed at the periphery of the cervix parallel to the cervical canal and approximately 1 cm. apart (fig 1). These are filtered by 0.5 mm. of platinum, are 21 mm. long and have an active length of 15 mm. Two to four 2 mg. needles are placed in each broad ligament beginning at the periphery of the cervix and extending outward and backward to the pelvic wall.

The proximal ends of these needles are placed about 1 cm. apart. Each is threaded with fine monel metal wire to facilitate its removal. A rubber tube with a wall thickness of 2 mm. containing two to four radium tubes in tandem is placed in the cervical and uterine canal in such a manner that the highest tube contains

Distribution of Gamma Roentgens to Points in the Pelvis

Approximate Roentgen Dose from Ring of Needles and Needles in the Broad Ligaments		Uterine Tubes		
		G	D	H
10 1 mg. needles active length 15 cm.	0.5 mm of platinum	17,000	1,500	800
3 tubes active length 60 cm.	15 mm of platinum	7,000	5,000	1,500
4 needles active length 36 cm.	0.5 mm of platinum		10,000	4,000
Total number of gamma roentgens		24,000	16,700	6,300
Total number of x ray roentgens		1,900	1,800	1,500
Total gamma and x ray roentgens		25,900	18,500	7,800

13.33 mg. of radium while the remainder contain 6.66 mg. of radium. The filtration of the tubes is 1.5 mm. of platinum and their length is 21 mm. Their active length is 15 mm. It is desirable to have the

radium tubes extend throughout the entire length (fig 2) of the uterine cavity. Gauze containing sulfanilamide crystals is then packed into the vagina in such a manner that the bladder and rectum are pushed as far as possible away from the radium. A self-retaining catheter is placed in the bladder. Following this gowns

Fig 5—Anteroposterior view showing position of radium tubes and needles

and gloves are changed and the abdomen is closed in the usual manner. The radium is left in position for approximately two hundred and sixty hours. An x-ray examination of the patient's pelvis both anteroposteriorly and laterally (fig 3) is made to ascertain the position of the radium containers.

It is surprising to find that patients are not more uncomfortable while the radium is in place, and it may be removed without the use of an anesthetic. Daily douches of potassium permanganate 1:5000 are given following the removal of the radium.

At the completion of the treatment the patient has had a total of 2,000 to 2,400 roentgens of external radiation to each of two anterior ports, 1,800 to 2,000 roentgens to each of three posterior ports and about 10,000 milligram hours of radium, all of which is given in a period of six to eight weeks. However, these figures in themselves mean little, so in an attempt to understand better the amount of radiation reaching various points in the pelvis one of us (J. W.) has computed the approximated dosage reaching pelvic points using the curves published by Patterson and Parker.⁷ Figure 4 indicates the dose reaching pelvic points which is close to that (fig 5) described by Sandler.⁸ From this it can be seen that the amount of radiation reaching the pelvic wall at least equals that estimated by Patterson and Parker as being necessary to kill cancer cells.

The central portion of the cervix receives approximately 45,500 gamma roentgens and the amount reaching points where the needles are placed 24,000 gamma roentgens, this corresponds closely to point C, which is 15 mm lateral to the cervical canal.

From the radium alone, 16,700 gamma roentgens reaches point D, 35 mm from the cervical canal, while 6,300 gamma roentgens reaches point H, 5 cm from the

cervical canal and 5 mm from the pelvic wall, a point which represents the position of some of the lymph nodes at the pelvic wall. If one then adds the number of x-ray roentgens to the gamma roentgens, one has a total of 25,900 at C, 18,500 at D and 7,800 at H.

Sandler has estimated the amounts of radiation reaching pelvic points by various techniques and it is seen that our technique enables one to deliver to the pelvic wall about as much radiation as his best figures (Manchester technique) show. According to his figures, the amount reaching C is 21,300, D 9,300 and H 4,950.

It is believed that the advantage in our technique lies in the fact that the size of the vagina has little influence on the treatment, while in the Manchester intracavitary technique it is most important.

From Jan 1, 1933 until Jan 1, 1942 we treated 52 patients who had carcinoma of the cervix. Several had very extensive disease. The primary healing of the cervix has been remarkably good. Little sloughing has been encountered and then only in the stage 4 cancers. No permanent damage to the bladder or rectum has been noted, although several patients have experienced a temporary proctitis. We have recognized no ureteral injuries. One patient had an elevated temperature for weeks, apparently due to low grade pelvic inflammation which may have been set up by the implantation. Some of the abdominal incisions have been slow in healing.

Of the patients that we have so treated 23 are dead, 15 died within one year of treatment and 7 died between one and two years after treatment. One lived three years. Twenty-nine are living. One is alive and well for more than eight years. Three are well after four years and 10 are living and well one year or more. There are 15 living less than a year after treatment.

The number of patients and the length of time involved, as well as the fact that at first nearly all the

Fig 6—Anteroposterior view showing position of radium tubes and needles

patients treated had very advanced carcinoma, make it impossible to give a picture in percentages that adequately indicates its value. The immediate response to treatment has been better than we experienced with the intracavitary method, which had been used before this. We now use it in all our stage 2 and stage 3 and in some stage 4 cancers.

⁷ Patterson R. S. and Parker H. M. *Brit J Radiol* 7: 82 (Oct) 1934.

⁸ Sandler B. *Brit J Radiol* 14: 284-293 (Sept) 1941.

We have used a method of interstitial and intracavitary radiation supplemented by external irradiation for the treatment of carcinoma of the cervix and its extensions whereby in the patient of average size an amount of radiation considered cancericidal reaches the lateral pelvic wall without increasing the dosage at and immediately adjacent to the cervix to such a point that necrosis of tissue is produced.

ABSTRACT OF DISCUSSION

DR A. N. ARNFSOHN, St. Louis. In this interesting report on the treatment of cervix cancer the aim has been to improve the amount of radiation reaching the outlying tumor-bearing regions. To accomplish this both x-rays and radium were employed with the addition of laparotomy at the time of radium treatment. It is difficult to understand how laparotomy will contribute materially to improvement in doses delivered by radium. It is obvious that by intra-abdominal palpation combined with vaginal examination one can gain a more accurate interpretation of the extent of the lesion. The iliac glands, however, are not always accessible for radium implantation from below. Greater knowledge of the outlying tumor-bearing regions may not therefore contribute to an improvement in clinical results. The risk of laparotomy is not small particularly in conjunction with radium treatment. The authors have pointed out that Pitts and Waterman used the intra-abdominal method at one time but abandoned it later. Trussig has reported on the use of gold seed inserted into the iliac regions but that procedure was eliminated because of sequele. It will be interesting to follow the work of Dr. Teahan and his colleagues and learn whether they overcome difficulties noted by other authors. Of significance in this report is the attempt to remove iliac nodes at the time of laparotomy. Trussig has reported considerable improvement in clinical results for such a method but the time factors involved in the sequence of procedures are quite different. Dr. Teahan has employed a four week rest period between the completion of x-rays and the application of radium at laparotomy. Trussig attempts to use a shorter interval and applies radium ten to fourteen days after iliac lymphadenectomy. I have believed that several advantages were to be gained by shortening the interval between x-rays and radium. Dr. Teahan and his collaborators have employed low intensity radium treatment. In some instances radium has been employed for periods of two hundred and sixty hours. In those instances total doses were on the order of ten thousand milligram hours. Pitts and Waterman employed comparable amounts at one time but I believe that they have now reduced their total doses. It would be interesting to know whether Dr. Teahan and his co-workers have noted any sequelae attributable to the radium treatment. The authors' method of treatment is not one to be advocated for general use but one which should be continued in their institution or in others equipped for investigative clinical work.

DR JOHN J. GILBRIDE, Philadelphia. I am going to speak on a subject that precedes the application of radium. The uterus is one of the most accessible organs in the body for examination. All forms of trauma are to be avoided. Careful inspection of the cervix is the first procedure. A biopsy is to be performed on any eroded or indurated area of the cervix of women above the age of 20 years, because we know that a small percentage of cases of cancer of the cervix occur in the third decade of women, and cancer of the cervix may occur in women under the age of 20 years. Early cancer of the cervix can be diagnosed only by the use of the microscope. The size, shape and mobility of the uterus can be determined usually by gentle palpation. The walls of the uterine cavity can be examined by the use of a cystoscope and, if necessary, a biopsy may be performed. The uterine curet does not have any place in the diagnosis or treatment of cancer of the uterus.

DR MISCH CASPER, Louisville, Ky. I wish to confirm some of the points made by the authors. Opening the abdomen is not the harsh thing it is thought to be. One can attack even metastases, and I don't think that these cases should be given

up if metastases are present. I have a case in which we used radium needles in metastasis to the ilium bone, with seven years' cure. The patient is still alive. We put the needles in from the abdominal side. Furthermore the lymph nodes can be attacked. There is another advantage in opening the abdomen. With the hormone relation to cancer lately established I think that removing the ovaries probably has some deterrent effect on recurrence, or certainly on the growth of cancer. In most cases one cannot determine with bimanual examination just what is inside the abdomen. Everybody who has opened many abdomens knows that one gets a much clearer view of the pathologic condition after the abdomen is opened. My experience differs from that of the authors in regard to treatment. They use radium for eleven days. I prefer to use it at intervals two days at most at one application and then repeat in several weeks the same amount, a larger amount or a smaller amount according to the indications. This may be done even the third or fourth time. I wish also to confirm the use of the x-rays in these cases, correlating the roentgens or radiation delivered by the two.

DR ROSCOE W. TEAHAN, Philadelphia. We feel that there is definite gain from opening the abdomen. We are much impressed with our inability to determine the extent of the disease by bimanual examination alone in many cases. We have been surprised at the intra-abdominal findings with the abdomen opened as compared with what we had thought was present before. This is a low intensity high infiltration technique and I think that the objections that have been recognized concerning the use of radon which is very lightly filtered, are overcome first from the standpoint of filtration and second from the standpoint of the needles being sufficiently long so that we feel we know more definitely where they are. I think that Dr. Arneson's question regarding the time lag is well taken. There is considerable question as to whether that much time should be allowed to elapse. In some of our cases we have been reluctant to open the abdomen sooner because of the condition of the skin. We have had no operative mortality in this group. This may be due to the fact that we do not have intra-abdominal infection because the roentgen treatment has cleared up the infection of the cervix before the abdomen is opened. Regarding sequelae we have not had an adequate number of patients for a sufficient length of time to tell about that. We have recognized no fibrosis of the uterus so far. In our follow up we are constantly on the lookout not only in these but in all our cervix patients for ureteral obstruction and infection of the cervical canal with a pyometra. There has been much argument regarding biopsy with its incident trauma. It seems to me that an accurate diagnosis is so important that it outweighs all other objections and I am very reluctant to treat a patient with cancer—resectable cancer—without having microscopic confirmation of the clinical diagnosis. Since the interval treatment requires another anesthesia and a reapplication of radium I prefer to avoid it.

The Shortage of Iron in Milk.—Milk is the only thing designed by nature solely for use as food yet it has some minor deficiencies. Most outstanding is the shortage of iron. The dietitians' recommendation is that you make up this deficiency by a daily supply of eggs, liver or spinach. But the content of iron in the different foods may vary considerably and cannot be relied upon for a definite amount. The chemist's natural reaction is that the proper way to supply the necessary daily dash of iron is in the form of a soluble iron compound which would be very inexpensive. Very finely divided metallic iron, ferric chloride, ferric ammonium citrate, ferrous sulfate and ferric pyrophosphate have all been found efficacious in varying degrees. A daily spoonful of a very weak solution of one of these compounds added to milk just before drinking it is the most painless way known to make up the iron deficiency at practically zero cost, though the taste is not all it should be.—Furnas, C. C., and Furnas, S. M. *Man, Bread and Destiny*, New York, Revnall & Hitchcock, 1937.

THE PRESENCE OF RELATIVELY AVIRULENT TUBERCLE BACILLI

IN PULMONARY TUBERCULOSIS IN MAN

II J CORPER, M.D.

AND

MAURICE L. COHN, Ph.D.

MAINT

Prior to 1898, the time when human and bovine tubercle bacilli were first differentiated by accurate biologic means, most of our conceptions of human tuberculosis and its origin were confused because of the lack of decisive experimental evidence on which interpretation could be based. So students believed that the type of disease and its organic distribution were determined largely by vague inherent readily changeable properties of the bacilli. Some of these unknown features were termed "virulence" or "pathogenicity," about which very little or no exact information existed. "Virulence" and "tubercle" were synonymous to them since the latitude of tubercle was not understood as it is regarded today, in the light of our modern advances in the knowledge of the reactions of specific immunity and its vital part in the interactions of the natural responses of tuberculosis.

Just twenty years later, however, in 1918,¹ it was possible to demonstrate by culture and by animal inoculation that all but two of eighty-two cultures directly isolated from the sputum of patients with active tuberculosis were sufficiently virulent to produce tuberculosis in guinea pigs within two months after the subcutaneous injection of 0.000001 mg of a culture. Of the two negative cultures one was entirely negative, not even producing tuberculosis with 1 mg amounts (except a local tubercle) and the other produced only slight tuberculosis with 0.001 mg amounts. Of the eighty-two cultures, eighty were of the human variety and one was definitely bovine while the other one was intermediate in its reactions and could not be placed definitely. As far as could be observed at the time there seemed to be no relation between the severity of the disease in man and the virulence of the bacilli.

In an extensive study on the behavior of tubercle bacilli within the body in 1936² it was shown that avirulent tubercle bacilli in amounts exceeding 0.001 mg in man and animals produce definite intracutaneous local lesions similar to those resulting from the injection of the same nonviable tubercle bacilli. Avirulent human or bovine (BCG) tubercle bacilli do not produce progressive lesions when injected intracutaneously in man and when injected in amounts capable of causing tubercle without ulceration lose their viability in these

lesions within about six months. Likewise, even large cutaneous local ulcers produced by avirulent human or bovine tubercle bacilli completely heal with scar formation in approximately six months. The reactions to viable avirulent tubercle bacilli in man, when used in amounts revealing visible changes, show a sequence of changed reactions on repeated monthly injections similar to the changes noted in animals and occur coincidentally with the development of specific immunity.

Thus we became better acquainted with avirulent tubercle bacilli. Calmette first scrutinized and evaluated, as far as possible for the time, BCG, an avirulent tubercle bacillus. He later used BCG for vaccination but before demonstrating its practical stability convincingly.

Not until 1937³ were universally avirulent tubercle bacilli defined accurately enough to differentiate them clearly from acid fast saprophytes on the one hand and virulent human and bovine tubercle bacilli of various grades of virulence (or pathogenicity) on the other. Three strains of avirulent tubercle bacilli (human and bovine) had been studied two from human sources (Trudeau R 1 and Human, Corper) and one (BCG) from a reputed bovine source. They could be differentiated only by their history, since they were all glycerophilic and defining biologic (animal pathogenic) differences were lacking. They still possess the ability of restricted growth temperature (approximately 37°C) an apparently stable property in contrast to acid fast saprophytes which grow in a wide latitude of temperatures. An avirulent strain of tubercle bacilli (human or bovine) was defined as a strain of tubercle bacilli lacking the ability to multiply in a highly susceptible host (such as the guinea pig) when injected intravenously in a fine suspension in amounts approximating the threshold of tubercle formation (0.01 to 0.001 mg produces a local tubercle) as is evident by the lack of gross tuberculosis or as the absence of metastatic gross tuberculosis following the subcutaneous or intracutaneous injection of relatively large amounts of a fine suspension of the bacilli (approximating 10 to as much as 500 mg). When properly tested, the property of avirulence or virulence of human or bovine tubercle bacilli was found to be stable consistently within a reasonable time, of many months at least, on artificial mediums or in the animal body. Changes in virulence of human or bovine tubercle bacilli appear to be a gradual transition and usually occur slowly over many generations of progeny of a pure strain. No guaranteed means of a ready or permanent transition appears to be available as yet, fulfilling the foregoing requirements for virulence.

In 1933⁴ observations were presented on the viability and virulence of old cultures of tubercle bacilli in furtherance of the report published in 1918 on the virulence of sputum strains. For this purpose forty-seven flasks were chosen containing human tubercle bacilli and nine containing bovine tubercle bacilli, planted in 1919 and 1920 and again studied after more than twelve years' residence in the incubator following their full growth in 1920. Among the human cultures representing seventeen different strains, twelve were recovered successfully by culture. Two of these were

avirulent human tubercle bacilli, one of them was designated "Bernstein" and was isolated from a patient at the National Jewish Hospital at the time (1919). Since the definition of virulence of tubercle bacilli was still vague to us in 1933, we preferred to call this organism "relatively avirulent" or "low virulent" even though we obtained negative results following the subcutaneous inoculation of 0.01 mg in guinea pigs. It was noted at that time that

it would appear that virulence is a property inherent and unchangeable in individual bacilli but prolonged cultivation on artificial media may cause a perceptible though not striking change in the progeny of human tubercle bacilli under the ordinary conditions of laboratory perpetuation on culture media.

At that time it was also noted in correlating culture findings with in vivo conditions that

the persistence of the bacilli in the body is dependent upon a number of factors, but prominent among these aside from the pathogenicity of the bacilli is the factor of the number of bacilli introduced into the organs and tissues of an animal. This is evident from the fact that while small numbers of virulent tubercle bacilli in fine suspension are removed from the organs and tissues of the rabbit and dog within about one

1941, when 41 per cent loss was noted. Sulfathiazole produced no improvement. Myringotomy in December 1940 had produced only scant drainage and discharge was of glue-like consistency.

Because of this and of the unfavorable progress as well as the history of previous active pulmonary tuberculosis, bacteriologic study was recommended with the following results: January 28 a specimen from the right ear collected by Dr. Laff yielded a positive tubercle bacillus culture at 37 C within five weeks on glycerin egg yolk medium, having given a negative reaction for acid fast bacilli on microscopic smear examination. A guinea pig inoculated at the same time and killed after two and a half months showed only slight local adenopathy and no other signs of tuberculosis. A virulence study was then made with the pure culture, and generalized tuberculosis did not develop in the guinea pigs following the subcutaneous or intravenous injection of amounts as large as 1 mg. Intravenous rabbit inoculations with amounts as large as 1 mg also resulted in negative findings for tuberculosis and thus excluded the possibility of a pathogenic avirulent tubercle bacillus or irregular bovine strain.

The patient was born in White Russia on Aug. 23, 1900. His father lived to the age of 82 and his mother died at the age of 45. Five sisters and brothers are all alive and well. He came to New York in 1921 and was ill in 1922. At that time he had a hemoptysis and entered Mount Sinai Hospital where

year, large amounts of even avirulent human tubercle bacilli can persist in the tissues of the dog in viable form for over three and a quarter years without the presence of characteristic histologic evidences of tuberculosis in these tissues.

Although our prior studies were initiated in line with classic academic objectives, the present report originated with a case which presented a simple diagnostic problem. The patient with evident tuberculosis presented himself to an otolaryngologist for an examination of the ears. Because of the possible implications of tuberculosis the specimen obtained was referred to us for bacteriologic examination.

History.—A man aged 35 visited an otolaryngologist (Dr. Herman Laff) on Nov. 25, 1940 with the complaint of stuffiness of the right ear and difficult hearing which had started two weeks before following a shower bath. The history given Dr. Laff at the time included pulmonary tuberculosis, an attack of iritis five years previously which improved after the extraction of a tooth followed by a second attack four years later which also improved. Examination of the right ear showed generalized redness of the tympanic membrane with a dull appearance and absence of light reflex. The whispered voice was 15 feet for the right ear and 20 feet for the left. The condition was first diagnosed as ordinary catarrhal otitis media. Treatment produced no improvement and hearing became worse. An audiogram on November 28 showed a 24 per cent loss of hearing in the right ear. Hearing diminished until Jan. 20

he remained for a number of weeks a right artificial pneumothorax being performed before coming to the National Jewish Hospital in Denver. After one and a half years' residence and discontinuance of pneumothorax he left the hospital in January 1924. The anatomic diagnosis during this time was pulmonary tuberculosis. Turban III B, a guinea pig inoculated with smear negative pleuritic fluid on July 21, 1923 had positive generalized tuberculosis when killed three months later. The roentgenograms taken at intervals proved interesting. In May 1923 there were good collapse of the right lung, exudative lesions throughout the entire lung, evidences of cavity in the apex and several long adhesions of the upper lobe to the chest wall. Although also involved the left lung was in fairly good condition (fig. 1). By July 1923 a pronounced collapse of the right lung had been attained and the left lung appeared to be clearing (fig. 2). By April 1925 after the right lung had been permitted to reexpand, the adhesions were not as evident in the roentgenogram, the right lung showed evidences of improvement while the left still was definitely mottled (fig. 3). A final roentgenogram, taken in May 1941 (fig. 4) showed the right lung mottled with cicatricial lesions and still not completely expanded, multiple adhesions were still evident and definite excavations in the upper lobe could be seen. The left lung also showed scattered calcified lesions and some apical excavations. After cultures from the ear proved positive, specimens of pulmonary sputum were obtained uncontaminated as far as possible by mouth and throat and 3 successive specimens proved positive for acid fast bacilli.

on microscopic smear examination and positive for tubercle bacilli on egg yolk culture. All three pure cultures (from 2 specimens of sputums obtained in April and the third in July 1941) were tested for virulence in guinea pigs and rabbits. None of these proved pathogenic for the guinea pigs or rabbits when given intravenously in amounts as high as 1 mg in fine suspension. The conclusion drawn from these virulence tests was that we were dealing in this case with an avirulent strain of tubercle bacilli.

Postmortem Examination—In April 1942 the patient died following a brief acute illness. Dr. Eli Nelson, who attended him at his last illness, said that he complained of indefinite pleuritic pain and general fatigue. Dr. Nelson sent him to the hospital for a check-up and rest five days before death. There was no pyrexia, although his general condition had not been good for some time; no definite findings except those pertinent to his old pulmonary tuberculosis could be noted. Twelve hours before death he became progressively weaker and showed a definite collapse-like reaction, which was then attributed to a cardiac effect in the absence of other manifestations. A postmortem examination performed by Dr. Irving Geever established the anatomic diagnosis of fibrocavernous tuberculosis in both lungs with chronic (compression) atelectasis of the right lung, extensive pleural adhesions to the upper lobe and cavitation of the upper portion of both lobes in the left lung. There were multiple small calcareous foci throughout both lungs.

Fig. 4—Chest plate of patient K. May 19 1941

Fig. 5—Chest plate of Bernstein Feb 5 1920

Fig. 6—Chest plate of Bernstein Jan 22 1942

The heart showed no abnormalities beyond a slight right hypertrophy, and the kidneys appeared normal, as did the adrenals. The significant pathologic changes were confined to the lungs which, aside from chronic fibrotic and calcareous changes, resultant compression atelectasis and atrophy of the right and compensatory hypertrophy of the left lung, showed a pronounced marginal acute hyperemia in the left lung not, however, attaining a pneumonic stage (fig. 6). Possibly the latter was the early result of a bacillary allergic reaction.

In view of the interesting findings regarding the presence of avirulent tubercle bacilli in this case and the earlier observations on virulence which had been carried on by us since 1918, we referred back to our data on the patient from whose sputum Bernstein tubercle bacillus was originally obtained and who was still available to us for further study. Briefly, the tubercle bacillus isolated in 1919 from the sputum of Bernstein was relatively avirulent in that the original sputum and the organism isolated from it in 1919 was sufficiently avirulent that no infection occurred in guinea pigs after the subcutaneous injection of 0.01 mg. This was verified in that the original strain, reisolated in 1933 from a culture made in 1920, was completely avirulent to guinea pigs tested in 1933 and 1942. As much as 1 mg. was given subcutaneously or intravenously without causing infection.

Clinical History—Bernstein, of Russian nativity (born in 1889), entered the National Jewish Hospital in 1914 with a notation that his disease was contracted in May, starting with a prolonged cold, loss of weight, slight pyrexia and mucopurulent sputum containing tubercle bacilli (in ear). The physical changes (rales, vocal fremitus, resonance and rough and diminished breath sounds) at that time were confined to the left apex and the right infraclavicular region. He was discharged with his condition pronounced arrested in 1915. The first roentgenogram of the chest was taken Feb. 5, 1920 (fig. 5) and showed slight mottling throughout both lungs with pronounced linear markings and a questionable small cavity in the left apex. The condition was apparently arrested at this time and the patient was performing the duties of a full time occupation. In 1941 he was still employed full time and was well. On Jan. 22, 1942 a roentgenogram of the chest (fig. 6) revealed a number of discrete small round foci in both lungs generally distributed throughout the parenchyma. The hilar shadows were pronounced and lung markings were accentuated to the right base. No cavity could be defined definitely. In the hope of recovering enough of his sputum for a culture, we took every precaution to obtain a pulmonary specimen uncontaminated by mouth and throat materials. After two unsuccessful attempts, a third specimen of sputum was obtained which was negative for acid-fast bacilli on microscopic smear examination, but a plant gave a positive culture after

about six weeks with the following results of infection tests. Intravenously 1 mg. killed the guinea pigs on an average of fifty days with a diffuse generalized miliary tuberculosis. Subcutaneously 1 mg. at three months produced a well defined local focus and tributary glands, multiple punctate lesions in the spleen, with no involvement of the other internal organs, 0.001 mg. produced at three months a slight involvement of the local and tributary glands, and an occasional animal would present a few splenic tubercles, smaller amounts than this did not produce tuberculosis. In comparison, a virulent strain of human tubercle bacilli given intravenously to guinea pigs would produce acute death in about sixteen days, while 0.000001 mg. subcutaneously would produce a massive generalized infection of all the internal organs of the guinea pig within three months (fig. 8).

Therefore, it is concluded that Bernstein's sputum in 1920 contained relatively avirulent tubercle bacilli incapable of infecting guinea pigs or rabbits under ordinary conditions, while the strain isolated in 1941 showed relatively mild virulence for guinea pigs but none for rabbits.

From these observations it appears likely that virulent tubercle bacilli from the patient with the usual active case of pulmonary tuberculosis might attain relative avirulence in their progeny, such slow transition resulting from continued growth in the prolonged

chronic case. The question was presented also whether tuberculosis in the chronic prolonged case may not be predominantly one of chronic allergic intoxication rather than predominantly tuberculosis. Our recent studies have contributed to the significance of this question by separating tuberculosis into the disease per se and tuberculous allergy, a separate condition.

Eight patients with advanced tuberculosis (sanatorium residents) with positive sputum whose histories disclosed ten years or more duration of their disease, were chosen to further this study. These patients were selected by Dr. Charles J. Kaufman from a hospital patient list of over 200. Culture isolations of the tubercle bacilli in the sputum were made on inspissated glycerin egg yolk medium and quantitative virulence tests were performed on guinea pigs with the primary cultures. Each culture was submitted to an accurate quantitative evaluation of virulence the details of which will be reported more fully elsewhere. The essential results however in the 8 cases are given in the accompanying table. In order to evaluate the brief virulence report which is given is the lethal result time following intravenous (en vein) injections of fine uniform suspensions 1 mg. being used as the standard amount of bacilli the control

cate a transition in virulence in the strain of bacilli carried by a patient with pulmonary tuberculosis over many years. However, it must be accepted that there is a possibility that tubercle bacilli can lead a vegetative existence in the cavities or certain parts of the chest

Fig. 5.—A comparison of the virulence of Bernstein strain 1941 with a recently isolated sputum strain (H 841) of virulent human tubercle bacilli. A (left to right) on one tuberculosis in guinea pigs three months after the subcutaneous injection of Bernstein strain 1941 in amounts of 0.1, 0.001 and 0.000001 mg. respectively. figures for each of three grades of bacilli are also tabulated and marked "control" under the strain designation.

It is unfortunate that data are not available at present beyond those presented in this study which would indi-

and that they may multiply there as they do in vitro in culture tubes. If this assumption is permissible there is no reason to believe that such an extravital existence of the bacilli may not result in a slow and gradual transition of virulence such as occurs in the culture tube under artificial cultivation. Even under these conditions, however, there can be no absolute guaranty that human or bovine tubercle bacilli will regularly become avirulent.⁴

With recognition of this it is interesting to note again that the majority of human tubercle bacilli isolated from patients with acute active pulmonary tuberculosis are highly virulent. Thus it is interesting to note also that the series of cultures isolated from the 8 patients with chronic pulmonary tuberculosis of over ten years duration showed 50 per cent of the cases graded as moderately virulent human tubercle bacilli while the other 50 per cent proved highly virulent. Although we realize that this series is not large the problem of the transition over years in the same patient is of great importance, and it is with the hope of initiating such investigations that this report was undertaken. There is another deduction to be drawn from this entire study, however, and that is that the presence of tubercle bacilli (not acid-fast saprophytes) in the sputum of a patient with advanced pulmonary tuberculosis presents no evidence that such tubercle bacilli are virulent. With regard to patient K, whose sputum contained large numbers, the tubercle bacilli proved incapable of infecting animals (universally avirulent), while the tubercle bacilli of Bernstein were relatively avirulent.

SUMMARY AND CONCLUSIONS

1 In 1918 it was shown that the majority of patients with open active clinical pulmonary tuberculosis who are residents in a tuberculosis sanatorium harbor virulent tubercle bacilli in their sputum.

2 Since then it has been possible to define avirulence and virulence of tubercle bacilli more accurately and to follow the course of several patients harboring relatively low virulent bacilli over several decades. In 1 instance, the strain of mammalian tubercle bacilli was carried for over twenty years, and the bacilli were again isolated from the patient twenty-one years after the first isolation and study. This strain, though originally relatively avirulent, has developed a low grade of virulence in the patient. In the second case, in which the tubercle bacilli were virulent enough in the pleural fluid eighteen years ago to infect animals, on recent isolation from the sputum and ear they proved avirulent. The extravital existence of the bacilli in the excavated lung of the patient appears to parallel similar laboratory cultivation in that some artificially cultivated bacilli tend to become less virulent, or in special cases become virulent. This patient, however, became acutely ill with the infection caused by the avirulent tubercle bacilli and died apparently not from tuberculosis but from tuberculous allergic bacillary intoxication caused by the large amounts of avirulent tubercle bacilli harbored in the lungs.

3 In an effort to establish whether chronic open cases of pulmonary tuberculosis of long duration harbor attenuated tubercle bacilli in any number, 8 selected patients with open pulmonary tuberculosis were chosen. Cultures of the tubercle bacilli isolated from their sputums were submitted to graded comparative virulence tests. Half of the strains from this series proved highly virulent and the other half were only moderately virulent. The series, however, is too small to draw general conclusions beyond the fact that the presence of tubercle bacilli in the sputum does not warrant deduc-

Results of Accurate Quantitative Evaluation of Virulence

tions regarding their virulence without actual submission of the bacilli to graded virulence tests. It suggests the possibility of a gradual diminution of virulence of a case over a period of years. Further studies appear desirable.

4 From these studies, the prognostic significance of the presence of tubercle bacilli in the sputum must be guided by three factors at all times: specific immunity to tuberculosis, which cannot be gaged at present in the individual case, the number of bacilli in the lungs, which may be approximated, and the virulence of the bacilli, which can be tested.

IS THE ASTHMATIC PATIENT
A GOOD SURGICAL RISK?

FRED W. GAARDE, M.D.

LOUIS E. PRICKMAN, M.D.

AND

HARVEY J. RASZKOWSKI, M.D.

Fellow in Surgery Mayo Foundation

ROCHESTER, MINN.

As it is often necessary to subject patients with asthma to major surgical procedures, it is of interest and importance to know the incidence of postoperative pulmonary complications and the apparent mortality risk in such a group. Therefore a study was made reviewing 189 consecutive cases of allergic asthma and asthmatic bronchitis in which major operations were performed at the Mayo Clinic between July 1934 and September 1940. The series consisted of 101 cases of predominantly allergic asthma and 88 of asthmatic bronchitis. The major surgical procedures carried out in our cases of asthma varied greatly.

In considering postoperative complications, only pulmonary complications were included in this study. In 25 (13.2 per cent) of the 189 cases some form of pulmonary complication (including severe asthma) developed after operation, as shown in the table. There were 10 cases of postoperative pneumonia (5.3 per cent), 9 of severe asthma (4.8 per cent), 3 of bronchitis (1.6 per cent), 2 of atelectasis (1.1 per cent) and 1 case of pulmonary infarction (0.5 per cent). Of the 10 cases in which pneumonia developed, a pre-operative diagnosis of allergic asthma had been made in 4 and a diagnosis of asthmatic bronchitis in 6. In 8 of the 9 cases in which severe bouts of asthma occurred postoperatively, a diagnosis of allergic asthma had been made and in 1 a diagnosis of asthmatic bronchitis. Bronchitis occurred postoperatively in 2 cases of allergic asthma and in a case of asthmatic bronchitis. Pulmonary infarction occurred in 1 case of asthmatic bronchitis. One case of atelectasis occurred in each classification. Generally speaking, the occurrence of pulmonary complications after operation on patients who had allergic asthma and those who had asthmatic bronchitis was about equal.

For the general population, the incidence of pulmonary complications after operations in the upper part of the abdomen is approximately double the incidence after operations on the lower part of the abdomen. This has been attributed to the reduction in vital capacity, which is greater after procedures on the upper than on the lower part of the abdomen. This difference was even more apparent when comparison was made of the incidence of pulmonary complications in our cases of asthma after surgical procedures on the upper or lower parts of the abdomen. When postoperative asthma was excluded as a complication, pulmonary complications developed in 15.1 per cent of the cases of asthma in which operations were performed on the upper part of the abdomen, whereas the incidence was 5.4 per cent of those in which operations were lower in the abdomen. When postoperative bouts of severe asthma are included, the incidence increased to 24.5 per cent in the upper abdominal cases as against only 7.1 per cent in the lower abdominal cases. It would appear significant, therefore, even in this small

series of patients having asthma, that the incidence of postoperative pulmonary complications is much increased after operations on the upper part of the abdomen. It also will be noted that asthma developed as a postoperative complication in more cases after operations in the upper abdominal region.

It should be emphasized at this point that 164 patients having asthma (86.7 per cent) underwent major operations without development of any significant pulmonary complication. It is unfortunate that the incidence of postoperative pulmonary complications in an otherwise identical nonasthmatic group of patients is not available for comparison, but it is felt from the data available that well considered necessary surgical procedures may be carried out on asthmatic patients who are otherwise in good condition, without great or prohibitive risk.

As an illustration the repair of a diaphragmatic hernia in a case of asthma was accomplished without pulmonary complications. The same patient success-

fully underwent resection of the ascending colon for carcinoma two years later, again without pulmonary complications. Since this series was completed, another allergic patient having hay fever and asthma submitted to repair of a diaphragmatic hernia. This patient was hospitalized preoperatively in a pollen free room near the termination of her hay fever season. She was found sensitive also to orris root contained in her dusting powder and to feather dust. Preliminary to repair of the hernia, each patient was subjected to temporary interruption of the left phrenic nerve, which resulted in elevation and fixation of the left half of the diaphragm. In spite of this handicap to normal respiration and the subsequent huge operation necessary to repair the diaphragmatic hernias, both patients got along remarkably well. The second patient had a little asthma postoperatively, and this was readily controlled by ephedrine and epinephrine.

A second patient died three days following resection of the posterior pulmonary plexus after the method described by Reinhoff and Gay.¹ The operation was performed in an attempt to relieve intractable, severe and continuous asthma of many years' duration. Severe emphysema had developed secondarily. In the present state of our knowledge of the treatment of severe asthma, this patient had nothing further to look for except distressing invalidism from his asthma. He had tried unsuccessfully the gamut of asthma remedies. Operation was undertaken reluctantly because the extreme risk was recognized by the consulting physicians and surgeons as well as the patient, who was willing and anxious to accept the risk on the slight possibility of obtaining some degree of relief. After operation severe shock developed, from which the patient recovered slowly. On the second and third postoperative days during episodes of coughing a right femoral hernia developed, this was reduced each time. The patient died the third day after operation. The chief pulmonary observations at necropsy were bronchitis, bilateral bronchiectasis and emphysema.

A third patient died five days following operation from a suppurative mediastinitis after the removal of an esophageal diverticulum. This patient experienced some asthma after operation, but asthma itself did not contribute to the patient's death as far as could be observed.

A fourth patient, a man aged 58, died of pneumonia seven days after cholecystectomy and exploratory cholecystostomy were performed for chronic ulcerative cholecystitis and cholelithiasis complicated by hepatitis and pancreatitis. He had had long-standing asthmatic bronchitis, and for this reason operation was delayed for two weeks until his cough and asthma could be better controlled. When maximal improvement seemed to have been attained he was operated on with spinal anesthesia, but in spite of oxygen therapy the splinting of the lower portion of the thorax proved fatal because of the development of bronchopneumonia. A more favorable outcome might have resulted if the sulfonamide drugs had been available at that time to combat respiratory infections.

The asthmatic patients in this series received special preoperative and postoperative consideration in an

In spite of this handicap to normal respiration and the subsequent huge operation necessary to repair the diaphragmatic hernias, both patients got along remarkably well. The second patient had a little asthma postoperatively, and this was readily controlled by ephedrine and epinephrine.

In the entire group of 189 patients having asthma and undergoing surgical procedures, only four deaths occurred, a mortality rate of 2.1 per cent. One patient developed severe asthma immediately after transurethral prostatectomy for benign prostatic hyper trophy with retention and died suddenly. He was

1 Reinhoff, W. F. Jr. and Gay, L. N. Treatment of Intractable Bronchial Asthma by Bilateral Resection of Posterior Pulmonary Plexus. Arch. Surg. 37: 456-469 (Sept.) 1938.

attempt to minimize postoperative pulmonary complications. All patients who had had recent colds were denied operation until they had completely recovered from the infection. Before being subjected to operation, patients with acute severe asthma were hospitalized preoperatively until the asthma was under better control. Most patients with asthmatic bronchitis received iodides routinely for several days before operation, and in certain instances iodides were administered postoperatively by rectum. In an occasional instance, chronic nondraining paranasal sinus infection was treated and adequate drainage established before proceeding with the major surgical operation. Allergic surveys in many cases furnished information useful in the preoperative and postoperative care of these patients. The patients were particularly questioned about idiosyncrasies to various drugs, anesthetics and serums and the professional and nursing staffs were cautioned not to administer drugs to which the patient had a known or suspected sensitivity. Other allergic precautions included placing patients who were sensitive to pollen in a room furnished with a pollen filter in the window, when operation was undertaken during their hay fever season, and the use of dustproof covers on pillows and mattresses or the use of air mattresses when indicated. The change to hypoallergic dusting powders, soaps and cosmetics was indicated and carried out in a number of instances. It was occasionally necessary, for allergic reasons, to omit certain foods from the patient's diet in which case an attempt was made to provide suitable substitutes and supplements.

The type of anesthetic agent to be used was given thought and ether anesthesia was avoided whenever possible. Ether, however, had been administered in 7 of the 25 cases in which pulmonary complications occurred. Patients were placed in an oxygen tent on returning from the operating room when their asthma seemed to warrant it. It is only by careful preoperative and postoperative care and proper selection of patients for operation and the all important, close cooperation between the medical and surgical consultants looking after these patients that a low morbidity and mortality rate can be attained in these cases when anesthesia and operative procedures are required. In emergency surgical treatment it is not always possible to prepare patients along ideal lines, but for all elective operations all possible precautions should be carried out carefully. A large majority of these patients received treatment before the sulfonamide drugs were available. Carefully administered, these drugs not only should increase the safety of necessary operation in the presence of asthmatic bronchitis but conceivably might make it possible to undertake surgical treatment in cases in which it might otherwise be contraindicated by asthmatic bronchitis.

CONCLUSION

It seems that the risk of operation on patients who have asthma and asthmatic bronchitis and have received adequate preoperative and postoperative care is not great, as 86.7 per cent of our patients underwent major operations without developing significant pulmonary complications. Patients with asthma and asthmatic bronchitis who undergo operations on the upper parts of the abdomen, however, are more likely to have postoperative pulmonary complications, including exacerbations of severe asthma, than those who undergo operations on the lower part of the abdomen. Postoperative pneumonia, bronchitis and severe asthma were the more common complications encountered.

ABSTRACT OF DISCUSSION

DR LESLIE N. GAY, Baltimore. During the past twenty-two years many patients in my clinic at the Johns Hopkins Hospital have been relieved by surgery of diseased gallbladders, pelvic tumors, acutely or chronically inflamed appendices diseased and often obstructing thyroid glands, and chronic infections of the antrums. The authors specifically mention that "ether anesthesia was avoided whenever possible." I prefer ether because of its stimulating effect on the heart. Avertin with amylene hydrate and pentothal sodium cause respiratory depression and shallow breathing, both undesired in the asthmatic patient. Gray and Riehoff published in the May issue of the *Bulletin of the Johns Hopkins Hospital* an article entitled "Further Observations on the Treatment of Intractable Bronchial Asthma by Bilateral Resection of the Pulmonary Plexus." Bilateral interruption is necessary to obtain what might be described as the expected physiologic result. The mechanism involved in severe asthmatic attacks is not only a constriction of the bronchi with the consequent increase in the resistance to inflow and outflow of air in the lungs. Constriction by spasm may play an insignificant role. There is also an excessive secretion from the bronchial glands of the patient with chronic asthma. The mucus becomes tenacious and inspissated actually plugging both large and small bronchi, and not infrequently there is edematous swelling of the mucous membranes of the small bronchioles. These findings have been confirmed by a study of the autopsy material of 50 asthmatic patients who have died in the hospitals in Boston and of 25 who have died in the Johns Hopkins Hospital. The 21 patients operated on had suffered with violent attacks of asthma in periods varying from one to twenty-eight years. The duration of the disease had no apparent effect on the therapeutic success of the operative procedure. One patient, 39 years of age, had suffered with asthma for twenty years, since the operation eight years ago she has never had an attack of asthma. The ages of the patients seemed to have no relation to the outcome, the youngest was 25 and the oldest was 55. These patients suffered with asthma of intrinsic type, the result of chronic respiratory infection and the subsequent infection of the pulmonary system. Allergy from extrinsic factors apparently played little part in the production of the asthmatic paroxysms.

DR GEZA DE TAKATS, Chicago. Bronchial spasm and increased bronchial secretion may occur even in nonasthmatic patients following or during operations. For several years, now, in the experimental laboratory my associates and I have been interested in vagal reflexes which may originate in the upper abdomen or in the chest. Thus, after a normal bronchial pattern is obtained in the dog, traction on the cystic duct, traction on the stomach, may produce a pattern characteristic of bronchospasm which can be readily abolished by atropine or bilateral vagal section. It has been found that if carefully looked for partial atelectasis occurs not infrequently after upper abdominal operations, as high as in two out of each thousand patients undergoing laparotomy. It is our feeling that anesthetics which have a vagal or a parasympathetic action, such as pentothal sodium and cyclopropane, facilitate these reflexes and that ether would be the best anesthetic. It interested me that the authors preferred not to use ether anesthesia. Experimentally, ether is the drug which most readily abolishes these reflexes.

DR L. E. PRICKMAN, Rochester, Minn. Both Dr Gay and Dr de Takats question the advisability of trying to avoid ether in operating on asthmatic patients. It has been my clinical impression that ether produces some bronchial irritation and aggravates coughing and thereby asthma, and that it should be avoided especially in cases in which asthma is secondary to bronchitis. Ether was administered to 7 of the 25 patients in our series who had postoperative pulmonary complications. It was a privilege to have Dr Gay review his and Dr Riehoff's experience in the surgical treatment of severe asthma. Their results are encouraging and the operation which Dr Riehoff has been doing should be kept in mind in attempting to help the patient with severe chronic asthma. The unfavorable result obtained from this operation in 1 case in our series certainly is not going to discourage me from considering it when I feel that the asthmatic patient is in serious condition and has exhausted all the usual methods of obtaining relief from asthma.

SOME CLINICAL USES OF PAPAVERINE
IN HEART DISEASE

STEPHEN R. ELEK, M.D.

AND

L. N. KATZ, M.D.

CHICAGO

Papaverine is an opium alkaloid of the benzylisquinoline group of low toxicity and non-habit forming.¹ At the present time its widest clinical use is in the treatment of conditions associated with smooth muscle spasm, e. g. peripheral vascular embolism, pulmonary embolism,² Raynaud's disease³ and ureteral or other types of tubular spasm.

We have recently investigated its action on the dog's heart and have found that it is a powerful and lasting coronary vasodilator⁴ that it diminishes considerably the ease with which ventricular fibrillation is induced by faradic or other type of stimulation and that after its administration vigorous manual massage of the heart will restore orderly synergic beating to the fibrillating ventricles.⁵

Further studies on the dog's heart⁶ revealed that 1. Papaverine in large doses depresses auriculoventricular and intraventricular conductivity leading to auriculoventricular and intraventricular block. 2. It decreases or eliminates ventricular premature beats induced at either a fixed part or different parts of the cardiac cycle. 3. It enhances the difficulty of producing or maintaining auricular fibrillation by means of a faradic current. 4. It prolongs the refractory period of the myocardium. 5. In toxic or nearly toxic doses it causes active ectopic ventricular rhythms, including premature systoles, paroxysmal tachycardia, flutter or fibrillation, or cardiac standstill or complete auriculoventricular block; its toxic action is more apt to occur in hearts that are ischemic. 6. All these effects are primarily direct ones on the heart. These results suggested that the beneficial action of papaverine in reversing artificially induced ventricular fibrillation and in diminishing or abrogating experimentally produced ventricular premature contractions is due to its depression of conductivity and irritability and to its prolongation of the refractory period of the ventricles.⁷ We have suggested that this action of papaverine and its coronary dilating effect would make it useful clinically in coronary insufficiency and myocardial infarction.⁸ It has recently been shown in experiments on dogs that the administration of papaverine reduces the mortality resulting from experimental ligation of a major coronary artery.¹⁰ Likewise our experimental demon-

stration that this agent reduces or effaces induced premature contractions⁹ suggests the possibility of its clinical value in the treatment of premature beats.

In this communication results of clinical studies with papaverine are presented. We have investigated the clinical effects of this drug in man on the anginal syndrome and on premature systoles. In the latter condition the effect of the drug was studied both when given intravenously and when given orally.

EFFECT OF PAPAVERINE ON THE
ANGINAL SYNDROME

The intravenous use of papaverine for the anginal syndrome was first suggested by Pal¹¹ in 1913 and in 1922¹² he reported beneficial results in 2 cases following the administration of 1.3 grams (0.075 Gm.) intravenously; severe attacks were relieved in both but the effect was lasting only in 1 of them. Meyer and Gottlieb¹³ referred to the intravenous use of this drug as a coronary vasodilator in angina pectoris but cited no cases. Macht¹⁴ in 1916 gave 0.6 gram (0.03 Gm.) papaverine sulfate by vein to 5 cardiac patients and noted temporary alleviation of the pain. Dopffel and Kutschera-Aichberger¹⁵ have administered large but safe doses (2 to 5 grams [0.13 to 0.3 Gm.] at a single dose and up to 30 grams [2 Gm.] daily) of eupaverine which is as potent as papaverine to several patients with severe angina pectoris and found a definite decrease in the anginal pain. Boehm¹⁶ found that a combination of cadcehol and camphor derivative (2 grams) and papaverine (½ gram) orally often caused the anginal attacks to disappear entirely. Kohn¹⁷ used papaverine in doses of 0.6 gram three times a day by mouth in patients with angina who failed to respond to drugs of the caffeine group. Evans and Hoyle¹⁸ have published a careful study of 90 patients with angina treated for two years with a wide variety of drugs; papaverine given orally (0.4 gram [0.026 Gm.] three times a day) was one of four drugs which had slight value. In our experience this dosage like the dosage employed by most of the other authors, is too small.

The difficulties in evaluating the efficacy of any drug in the oral treatment of the anginal syndrome have recently been emphasized.¹⁹ Sources of error reside in the method used in evaluation in the subjective reactions of the patient in the unwitting prejudice of the examiner and in the spontaneous remissions of the disease. We have attempted to avoid these pitfalls as far as possible.

Method—Our procedure of evaluating the drug action was similar to that employed by Evans and Hoyle.¹⁸ Well established cases of the anginal syndrome previously treated in the cardiac or medical clinics for from six months to several years were selected. A complete history (including social and family background) and a physical examination were made and requisite laboratory data were available in

the charts of all the patients, this information having been obtained during their previous attendance at the clinic and supplemented by us.

A control period of two to four weeks without any medication (except glyceryl trinitrate²⁰) or with the placebo (tablets of ordinary lactose) was established, particular emphasis being placed on the following cardinal features: (1) the number of anginal attacks daily, (2) the duration of each attack, (3) the severity of each attack, (4) the degree of activity indulged in during an attack, (5) the average number of blocks that the patient could walk in a day before precordial pain occurred and (6) the number of tablets of glyceryl trinitrate used a day or week to alleviate severe pain. For this purpose, the patient kept a daily diary, which was submitted at each clinic visit. This was carefully reviewed with the patient, who was also interrogated in regard to his degree of well-being, to his reaction to the medication, to the weather conditions and to any change in his habitual status, e. g. daily activities and emotional upsets. Usually a single examiner inter-

lactose. The papaverine tablets are about three times as large as the placebo tablets, but the patient was assured that a small pill may be as potent as a large one by virtue of concentration. This assurance overcomes in part any bias that might arise in the patient's mind because of a difference in size of the two pills. The careful diary and regular interrogations were continued throughout the study.

The cardinal features mentioned were summarized for each course of treatment, and a daily graph was made so that a pictorial impression might also be obtained. In this way the effects of placebo and papaverine were compared for one or more periods of trial by subjecting the patient to them in succession. Sometimes a clear effect could be demonstrated by a reduction in the frequency of anginal attacks alone, or by an increase in the number of blocks walked (if angina pectoris occurred only after walking), at other times all these features had to be combined in order to obtain the net effect. It is obvious that the regularity and attention associated with this type of study may in

E H	59	Hypertensive and arteriosclerotic heart disease diabetes mellitus	5	6	5	4	Inconclusive

Each course usually lasted two weeks occasionally three weeks and was alternated between periods of placebo and periods of papaverine or a placebo period preceded and followed each papaverine period when a period without any medication interrupted the observations. In each instance there was a variable period up to four weeks in which the patient was educated to the procedures before starting the actual courses. Throughout the study glyceryl trinitrate in minimal quantities was permitted.

viewed the patient, but occasionally another observer was substituted as a check.

The diary not only adds objectivity to this method of study but also places a great share of the clinical analysis on the patient, thereby encouraging faithful and accurate reports. Thus if a patient did not recall his reactions to either medication or his diary entries during the previous interval, these data were read to him, stressing in this way the importance of an accurate diary. The control period also furnished information about the reliability and the degree of cooperation of the patient.

After this control period the unreliable and uncooperative patients were eliminated. The others were started on 1½ gram (0.1 Gm.) tablets of papaverine hydrochloride²¹. This was given four times a day—before meals and before bedtime. This strength is greater than that recommended conventionally,¹ but our experience fully justifies this. Usually two weeks of placebo medication were alternated with a similar period of papaverine medication, rarely one or three week intervals were employed. Occasionally acetylsalicylic acid or codeine was given instead of the placebo of

itself alter the clinical manifestations independent of the form of drug therapy. It is for this reason that periods of papaverine were alternated with periods of placebo. In some cases this attention and diary keeping led to progressive improvement, but even here the special benefit of papaverine was revealed (cases 1 and 2).

The patients were grouped into (1) those who were definitely improved, (2) those who were slightly improved and (3) those who showed inconclusive results. While quantitation is obviously not possible, definite improvement was found to be characterized by a reduction of 25 per cent or more in the number of anginal attacks in a period of study, a consistent increase of 50 per cent or more in the number of blocks walked without pain occurring, a decrease of 50 per cent or more in the duration of the anginal pain or a reduction of 50 per cent or more in the number of tablets of glyceryl trinitrate used in a given period to alleviate the anginal attacks.

Results—A total of 17 patients were studied in this way, 11 men and 6 women varying in age from 52 to 72. (Observations are recorded in the accompanying table.) The duration of the history of angina pectoris before the study was started ranged from six months to fifteen years. These patients were kept under observa-

²⁰ Those patients requiring glyceryl trinitrate were instructed to reduce the number of tablets used to a minimum.

²¹ These were supplied by Eli Lilly & Co. through Dr. K. K. Chen.

tion for five to eleven months (averaging seven months) during this study and were observed in all seasons of the year. Twelve (70 per cent) of these 17 patients were definitely improved by papaverine, 2 (12 per cent) were slightly improved and 3 (18 per cent) were in the inconclusive group. Of the last group, 1 subject had only two courses of papaverine (too brief to obtain a consistent impression) but was definitely improved during the periods of papaverine medication. In 1 of the remaining 2 cases only two courses of papaverine were given, while in the other a spontaneous remission probably occurred.

In the slightly improved group, 1 patient showed definite improvement in three out of four trials with papaverine, and the other subject revealed improvement in four out of five trials.

A few cases are here briefly cited to illustrate the definite improvement that was observed.

CASE 1—J S, a man aged 63 with arteriosclerotic heart disease had had for fifteen years a persistently severe anginal syndrome. His habitual status consisted of twenty to twenty-five anginal attacks in a fortnight each lasting on the average fifteen to thirty minutes and requiring about 7 to 15 tablets of glyceryl trinitrate during the two week period. He was barely able to walk $\frac{1}{4}$ block. Electrocardiograms revealed no evidence of myocardial infarction. He received eight courses of placebo and six of papaverine medication. During the first course of papaverine medication he had less pain with each episode and could walk 2 to 3 blocks without the occurrence of anginal pain. There was no change in the frequency of anginal attacks but the duration dropped from fifteen to thirty minutes to five to ten minutes on the average. After the third course of papaverine the patient had seventeen anginal episodes as compared to twenty-three during the placebo course but without change in the duration of the pain. He used only 2 tablets of glyceryl trinitrate as compared to 7 while on the placebo, he walked 10 blocks as compared to 5 while on the placebo and suffered less pain with each attack. During the fourth course the patient had seventeen anginal episodes as compared to twenty-six while on the placebo, he took 2 tablets of glyceryl trinitrate instead of 6 while on the placebo, but there was no change in the average duration of the pain, he walked on the average 9 blocks instead of 6 while on the placebo and experienced less pain while walking. The patient was then able to indulge in a restricted amount of work for the first time in a decade, and despite this he had fewer attacks, which were of shorter duration and required fewer tablets of glyceryl trinitrate to alleviate the pain.

CASE 2—S B, a woman aged 57 with hypertensive and arteriosclerotic heart disease and status anginosus, had been treated for angina for only five months. During the first three weeks of observation the patient was hospitalized because she complained of intermittent substernal pain throughout the day or, when this was absent, she had two to three attacks a day, each lasting about one-half to one hour. Electrocardiographic study with serial records revealed no evidence of myocardial infarction. She usually took 1 to 2 tablets of glyceryl trinitrate a day and was barely able to walk about her home. When first placed on papaverine the patient had fewer attacks and less pain. During the second trial with this drug she had four anginal episodes as compared to sixteen while on the placebo, each lasting about fifteen minutes instead of the half hour while on the placebo, and she could walk 1 to 2 blocks. While subsequent trial with the placebo revealed continued improvement and the patient suffered fewer attacks compared with the first course of papaverine, a further period of papaverine following the placebo period showed still fewer attacks, of shorter duration, with less pain and an increase in her walking ability of from 3 to 5 blocks.

CASE 3—C C, a man aged 63 with arteriosclerotic heart disease, mild diabetes mellitus and angina only on effort, could walk only $\frac{1}{2}$ block without any medication and while receiving the placebo. This distance was almost constant, as it is the

distance between the patient's home and his place of worship. After the first course of papaverine he could walk 1 block without stopping. Subsequently, he walked 1 block while on the placebo but 2 to 3 blocks when taking papaverine, and this difference was consistently found during the rest of his six month period of study.

CASE 4—I B, a man aged 68 with arteriosclerotic heart disease and a five year history of angina pectoris, could walk only $\frac{1}{2}$ block during the control period on the placebo, but while on papaverine he walked $1\frac{1}{2}$ blocks. This improvement continued when he was on the placebo but when subsequent periods of papaverine were compared with the placebo periods it was found that he could walk 5 to 6 blocks while on the former and only 3 blocks while on the latter.

CASE 5—J S, a woman aged 52, a housewife with arteriosclerotic heart disease, mild diabetes mellitus and anginal attacks of three years' duration, had a habitual status of twenty anginal seizures a fortnight lasting about twenty minutes each, and she could walk only 1 to 2 blocks. After a course of papaverine she had only ten attacks in a fortnight, walked 3 blocks, had less pain and could perform more housework. This improvement was consistently noted during the eight month interval of observation when the placebo and papaverine periods were compared.

Comment—It is thus apparent that in the dosage used papaverine has a beneficial effect in about 75 per cent of the cases. Subjective reactions to the drug were similar to those to any drug from which benefit is derived. None of our patients showed any signs or symptoms of addiction and were easily able to get along without the drug. Our experience indicates that any fear of addiction because this is a drug derived from opium is groundless. Even when the drug was given in intravenous doses of 1 to 2 grams three times a week for six to eight months addiction was not manifested. Hence, in our opinion there is no basis for concern regarding the development of addiction, and there is therefore no reason for not continuing medication indefinitely, if indicated.

We have not determined whether smaller or larger doses of oral papaverine would have a similar or more salutary action on the anginal syndrome. One patient who received 3 grains (0.2 Gm) four times a day felt sleepy, but this reaction disappeared after the dose was reduced to $1\frac{1}{2}$ grains four times a day. Our studies on the treatment of premature systole (reported later) demonstrate that 3 grains four times a day may safely be given. Side reactions (e.g. ectopic beats) or unpleasant symptoms (e.g. sleepiness or constipation) did not occur in any of our patients. We have administered the drug before meals simply because little is known about its absorption and excretion. The lack of better results in the 31 cases of Evans and Hoyle¹⁸ is probably attributable to their small dosage.

While our series is admittedly small and the duration of treatment short, our results are definite enough to warrant the wider use of papaverine in the management of patients with the anginal syndrome. Already several private patients with the anginal syndrome have been treated with this drug at our suggestion and improvement was noted in all.

As to its mode of action papaverine has three possible effects which may contribute to its beneficial effect in preventing or relieving anginal attacks. 1 It has a mild sedative action and thereby dulls the perception of pain. 5 It has a definite and lasting coronary

22 According to Machi⁵ papaverine in man is unchanged in the body and is excreted chiefly in the urine bile and small intestine. On the other hand Goodman and Gilman⁴ state that it is not recovered from the excreta or tissues and that its fate in the body is unknown. The question certainly is not yet settled.

dilating action which should make for better coronary irrigation except in severe cases of narrowing.³ It could prevent or lessen the occurrence of premature systoles or rapid heart action of certain types which are known to lead to anginal pain. In this last respect it acts like but is superior to, quinidine, since it also has a coronary dilating action which quinidine lacks.²³ Furthermore, the coronary dilating and sedative actions of papaverine combine in one drug the advantages attributed to the antihistamine derivatives with that of a hypnotic such as phenobarbital. That sedation alone is not the sole mode of papaverine action is shown by the absence of effect of acetylsalicylic acid or codeine when used on several occasions instead of the placebo.

EFFECT OF INTRAVENOUSLY ADMINISTERED PAPAVERINE ON PREMATURE BEATS

As far as we know, there have been no clinical studies on the action of papaverine on ectopic rhythms in man. We therefore undertook to determine its effects when used intravenously in adequate doses. For this purpose, 23 patients with various arrhythmias were studied: 12 had premature systoles (6 of auricular origin and 6 of ventricular origin, 3 of the latter being attributable to excess digitalis) with and without fixed coupling, 8 had auricular fibrillation of which 3 were paroxysmal, 1 had a chronic auricular flutter, 2 had supraventricular paroxysmal tachycardia, and 1 had a complete auriculoventricular block with the idioventricular pacemaker above the bifurcation of the bundle.

Procedure—Each patient was placed at bed rest for about ten minutes and then a control electrocardiogram of one of the limb leads was taken. In addition, the cardioscope (Sanborn) was used to follow the effects of the drug. In the case of premature beats the cardioscope was run for about ten minutes to measure the frequency and site of origin, and these cardioscopic observations were continued following administration of the drug.

After the preliminary observations, papaverine hydrochloride was injected intravenously in different doses. We found it possible safely to administer much larger doses than conventionally recommended,¹ thus we have given $3\frac{1}{2}$ grams (0.23 Gm) in two divided doses of 2 and $1\frac{1}{2}$ grams within ten minutes. Usually, however, 1 to $1\frac{1}{2}$ grams was used and this could be repeated within ten minutes. Doses less than 1 gram we have found usually had no effect. Thus, as in the oral treatment of the anginal syndrome, the secret of success appears to lie in the employment of larger doses than previously given. This is in accord with the observation on eupapaverine,¹⁵ in which 2 to 5 grams in a single dose and up to 30 grams daily was given in cases of pulmonary embolism, angina pectoris and bronchial asthma without any ill effects.

Results—In the 6 cases of auricular premature contractions, papaverine diminished or abolished the ectopic rhythm in 4 cases for a period of from one to six minutes, in the other 2 cases it had no effect. In the 6 cases of ventricular premature systoles, tests were made with one to three injections of papaverine, a total of twelve doses. This caused a sharp diminution or abolition of the ectopic beats in every instance for periods of two to ten minutes, and in one instance (when used as a slow drip in saline solution, case 8) for several hours. There was a lag of up to three and

one-half minutes after injection before the papaverine action became apparent. In case 8, two preliminary doses of $\frac{1}{2}$ grain intramuscularly were without effect.

In 8 cases of chronic or paroxysmal auricular fibrillation, papaverine had no effect on the mechanism. In 4 of these, however, papaverine caused the transient occurrence (for thirty to sixty seconds) of ventricular premature beats usually from one focus, with or without fixed coupling. In the case of auricular flutter, 1 grain of papaverine intravenously had no effect on the mechanism but led to the transient occurrence of premature ventricular systoles and a bigeminal rhythm lasting about thirty seconds. In the 2 cases of supraventricular tachycardia, $1\frac{1}{2}$ grains of this drug had no effect in 1, in the other, however, it caused partial auriculoventricular block with the P-R longer than the R-R interval, so that the P was responsible for the second QRS-T following it. In the patient with complete auriculoventricular block 1 grain of the drug caused a temporary period of ventricular tachycardia lasting about ten seconds, from which the patient recovered without ill effects.

Several illustrative cases presenting ventricular premature systoles are worth reporting in brief.

CASE 6—E. J., a boy aged 12 years with mitral and aortic valvulitis due to rheumatic fever, with stenosis and regurgitation in each valve, showed auricular fibrillation and frequent ventricular premature systoles due to excess digitalis. When 1 grain of papaverine was injected intravenously the premature systoles completely disappeared for a period of ten minutes. Eight days later, with the arrhythmias still present, even though digitalis had been stopped, another 1 grain of papaverine was given intravenously and again the premature beats were abolished for nine minutes. One month later he was seen again after having been treated with digitalis in the interim. Auricular fibrillation and premature ventricular beats were present with an occasional bigeminal rhythm. One grain of papaverine was injected intravenously over a period of fifteen seconds and resulted in the disappearance of the premature beats for five minutes and a decided decrease in their frequency for another minute. In all three trials with this drug the auricular fibrillation was unaffected.

CASE 7—A. S., a man aged 55, had a sinus rhythm and frequent premature systoles from one ventricular focus giving rise to a bigeminal and quadrigeminal rhythm, this was caused by excessive doses of digitalis. He was given $1\frac{1}{2}$ grains of papaverine intravenously in twenty-five seconds, and following this the premature systoles disappeared for five and one-half minutes. The ectopic beats returned fifteen minutes after the drug was injected to their previous frequency and another $1\frac{1}{2}$ grains of this drug was administered, with a similar effect.

CASE 8—A. W., a man aged 55, was admitted to the hospital, in the private service of Drs. H. I. Sapoznik and Richard Langendorf in "shock" with clinical evidence of a recent myocardial infarct. The electrocardiogram revealed ventricular premature systoles from multiple foci occurring with great frequency (fig. 1). Two doses of $\frac{1}{2}$ grain each of papaverine given intramuscularly were without effect. Then, about one hour later, $1\frac{1}{2}$ grains of papaverine dissolved in 125 cc of 5 per cent dextrose and isotonic solution of sodium chloride was slowly injected intravenously. About twenty minutes later, after approximately 1 grain of the drug had been administered the electrocardiogram (fig. 2) revealed an almost complete absence of ectopic beats, only one being found in the entire long five lead tracing. Fairly continuous cardioscopic observation over the next twelve hours showed that the frequency of the premature systoles was definitely reduced. Shortly before the patient's death a brief run of paroxysmal ventricular tachycardia was noted which subsided. About fifteen minutes before death continuous cardioscopy revealed a slow regular rhythm of unknown origin, followed by cardiac standstill. Permission for autopsy was not granted.

Comment—Our experience with papaverine demonstrates clearly that its intravenous administration is valuable in temporarily reducing the number of premature beats or abrogating them entirely, this applied to those of auricular as well as of ventricular origin. However, papaverine appears to be more effective in

Fig. 1 (case 8)—Electrocardiographic tracing three limb leads and chest leads CF and CF₄ before papaverine was administered. Sinus arrhythmia. Tall P and P₄ and inverted P in chest leads. QRS1 configuration is suggestive of an atypical infarction of posterior wall. Frequent ventricular premature systoles from multiple foci at times interpolated at other times with bigeminal rhythm. Occasional nodal escape. Chaotic heart action.

depressing ventricular premature systoles. This property is especially advantageous in recent myocardial infarction, since the premature systoles represent an added burden on the heart and may, if of ventricular origin, result in fatal ventricular fibrillation. By reducing or abolishing the premature beats for a short period of time, one lessens these risks. There is no contraindication for its use in the presence of premature systoles since papaverine does not depress the heart, as is the case with quinidine, and its powerful and lasting coronary dilating action is an advantage. The blood pressure drop that occurs with papaverine⁴ is too small to be hazardous. In no instance did we find that it increased the frequency of the premature beats, although on two occasions it did not affect auricular premature systoles. There is no reason why it may not be administered intravenously repeatedly without risk, but this may be unnecessary since, as will be shown, oral administration can be used for continuation of the desired papaverine effect.

Papaverine has thus proved of no value in reversing paroxysmal or chronic auricular fibrillation, paroxysmal auricular flutter or supraventricular paroxysmal tachycardia. There is at present no indication for the use of intravenous papaverine in these ectopic rhythms, it appears to have no effect in abolishing them although more studies on this aspect of the problem are desirable. When the heart is depressed and premature beats are

absent, papaverine may at times lead to transient ectopic rhythms of ventricular origin, either premature beats or paroxysmal tachycardia. In this regard it is no different from digitalis or quinidine. Papaverine has the advantage over the latter drugs in that it may be injected intravenously in large doses with greater safety. In fact, it will abolish the premature systoles occurring when an excess of digitalis has been given. It is interesting that in the group of patients studied it caused acceleration of the sinus rate but not the idioventricular pacemaker and that in a few instances it resulted in intraventricular block and auriculoventricular block and caused the occurrence of premature systoles and paroxysmal tachycardia of ventricular origin—effects similar to those obtained in our studies in the dog.⁵ These undesirable but transient side actions suggest that intravenous papaverine should be used to abolish premature systoles (auricular or ventricular) only when their frequency and the state of the patient suggests that they are detrimental to his welfare. This is particularly the case after a recent myocardial infarct.

When an indication exists for the eradication or reduction of premature systoles occurring during the course of a recent myocardial infarct, or for the alleviation of a severe paroxysm of anginal pain, or when the desired action of intravenously administered papaverine is not attained by several discrete injections, it may be given slowly by intravenous drip in appropriate volume after being dissolved in diluted form in isotonic solution of sodium chloride or saline-dextrose solution (for

Fig. 2 (case 8)—Electrocardiographic tracing after 1 gram of papaverine was given intravenously by slow drip. Only one ventricular premature systole present (in CF₁).

example, case 8). This is advantageous in avoiding the occurrence of block or transient ectopic rhythms, since it is given in less concentrated form. There is the further advantage that the drip can be stopped at will when necessary if these undesirable effects occur. In addition, the beneficial effect can be protracted over longer periods when desired by this method.

EFFECT OF ORAL ADMINISTRATION OF PAPAP-
VERINE ON PREMATURE SYSTOLIC

The temporary abolition of premature systoles with intravenous papaverine suggested that oral administration might have therapeutic effects

Procedure—Five patients were selected for continuous observation and were hospitalized in order to obviate the variable factors which, in ambulatory clinic patients make it difficult to evaluate the action of the drug. The patients chosen were referred to us because of the persistence of frequent premature beats for long periods of time. Before being admitted to the ward the patients were examined on three or four occasions in the Heart Station to check the frequency and persistence of the ectopic beats. In 4 of our patients a careful history revealed that digitalis had not been taken at all or not for at least six months preceding our study. The admission to the hospital of the fifth patient was deferred for two weeks because she had taken 2 cat units of digitalis in the fortnight preceding her last visit to the Heart Station.

In the hospital the subjects followed the usual routine of patients not confined to bed. They were per-

Fig 3 (case 9)—Summary of protocol at right in frame are hourly observations on day that patient was on quinidine (arrows show time of administration of 3 grains). Ordinates below show percentage of premature to total beats either daily average or in frame hourly average above total grains of papaverine in a day

mitted to smoke, walk about, receive visitors and occasionally rested in the afternoon for an hour. They were on a full diet and received no medication other than the drug tested. After a suitable control period of two to seven days they were placed on papaverine hydrochloride for four to eight days. This was repeated twice in each case. The 1½ grain tablets, previously employed in the treatment of the anginal syndrome, were used. The usual dose given was 3 grains four to five times a day at three or four hour intervals, either before or after meals. No drugs were given in the intervals between papaverine medication.

The number of premature beats was ascertained for ten minutes, at the radial pulse by palpation, at the cardiac apex by auscultation or by cardioscopy, two or three times a day at approximately 9 a m, 12 30 p m and 6 p m. On several patients hourly observations were conducted from 9 a m to 9 p m toward the end of the study in order to obtain a better perspective of the variability of the ectopic beats in control periods and crudely to estimate the lag of papaverine effect and its persistence. For comparison, in several subjects, similar hourly observations were made with quinidine sulfate (3 to 5 grains orally three or four times a day).

The patients selected were 4 men and 1 woman between the ages of 45 and 69. Two showed clinical evidence of heart disease. Three were Negroes. In 3 the premature systoles were ventricular, in 1 both ventricular and nodal and in the last auricular.

Results—The data on the 5 cases so studied are summarized in figures 3 to 7. The results can best be presented by briefly describing each case.

CASE 9—S. J., a Negro aged 57, first felt skipping of the heart about eight months before admission and more frequently in the last few months. On Jan 20, 1942 bigeminal rhythm was noted during a visit to the Mandel Clinic and was confirmed by the electrocardiogram, which showed ventricular premature systoles with fixed coupling.

The patient had not received digitalis at any time. Physical examination gave entirely negative results and the blood pressure was normal. A teleroentgenogram showed left ventricular enlargement. The serologic examination gave negative results. The observations are summarized in figure 3.

During both periods of papaverine medication the frequency of premature beats decreased sharply, from an average of 47 per cent of all the beats, in each of the two control periods, to 15 per cent and 18 per cent during drug treatment. The action of papaverine disappeared in about twelve hours after cessation of treatment. Only in the first papaverine interval was there any tendency for the effect to become more pronounced as the drug medication was continued. The effect of quinidine was about as strong as that of papaverine during the single day it was tested.

CASE 10—A. M., a man aged 65, had arteriosclerotic and hypertensive heart disease and peripheral vascular arteriosclerosis. The heart was enlarged but no murmurs were present. The blood pressure was 160 mm of mercury systolic and 112 diastolic. Frequent premature systoles, first noted in November 1941, were confirmed by an electrocardiogram, which showed them to be from multiple ventricular foci, the patient was not aware of them. There was also a left axis shift in the electrocardiogram, and the teleroentgenogram revealed left ventricular

Fig 5 (case 11)—Summary of protocol at right in frame are hourly observations of three days on papaverine (arrows show time of administration of 3 grains). Conventions as in figure 3

enlargement and a calcific aorta. Serologic examination gave negative results. The observations of the effect of papaverine are summarized in figure 4.

While the results in this case appear to be less striking than in the previous one, nevertheless, on an actual percentage basis, the effect is about as great. Thus in the control period the premature beats constituted 9.5 per cent and 4 per cent of all the beats, but during papaverine treatment only 1.5 per cent. This represents a reduction of about one third and one sixth respectively, whereas in case 9 it was about one third.

CASE 11—L W, a Negro woman aged 49, was hospitalized elsewhere because of mild congestive heart failure. In March 1942 an electrocardiogram showed frequent ventricular and nodal premature systoles with coupling. The patient had felt a skipping of the heart since 1941, but this was not trouble some. She was found to have an enlarged heart on physical examination, an aortic valvular insufficiency and an Austin Flint murmur. Left ventricular enlargement was present in the teleroentgenogram and a left ventricular preponderance in the electrocardiogram. Serologic examination gave negative results but the cardiac findings suggested a syphilitic etiology. The observations on the effect of papaverine are shown in figure 5.

Unlike the former two, this patient showed a decline in the frequency of the premature beats on hospitalization. Nevertheless a further reduction following papaverine could be demonstrated. Thus, in the first control period in the ward the ectopic beats constituted 18 per cent of all beats while in the first papaverine interval they were only 4.5 per cent. In the

on March 5, where he stayed for sixteen days. He was then discharged, seen again on April 1 and 6 and readmitted to the ward for another period of study on April 11. During the first control period the premature systoles constituted 21 per cent of the total beats, on papaverine medication they decreased to 6.5 per cent—a striking effect. However, in the subsequent control interval their incidence became even less, 1 per cent. But when the patient was seen again on April 1 the premature beats were as frequent as before, and this was true also five days later. Hence it is fair to infer that part of the improvement was simply due to hospitalization, although our evidence inclines us to the alternative view that the effect of papaverine in reducing the incidence of the premature beats persisted. This is comparable to the alleviation of the anginal syndrome, which continues for some time after its abolition by glyceryl trinitrate until some episode initiates it again. There is no reason to doubt that interfering with the chain of events causing premature systoles may bring about a decrease in their frequency which outlasts the period of drug administration. There is no

Fig 6 (case 12)—Summary of protocol at right in frame are hourly observations of two days on quinidine two days on papaverine and one control day (arrows show time of administration of 3 grains of quinidine and 3 grains of papaverine respectively). Conventions as in figure 3.

Fig 7 (case 13)—Summary of protocol at right in frame, are hourly observations of three days on papaverine one control day and two days on quinidine (arrows show time of administration of 3 grains of papaverine and 3 grains of quinidine [the first dose on May 14 was 6 grains] respectively). Conventions as in figure 3.

two days of the second control period, the premature beats were still 4.5 per cent, but they decreased to 1.5 per cent in the second papaverine period. The results are not as definite as in the other cases and further observations after papaverine was stopped would have been desirable, but this was not possible because the patient left the hospital against advice. On the right hand side of figure 5 are plotted the hourly readings on the first three days of the second papaverine period to show the narrow range of scatter of the observations.

CASE 12—A F, a Negro aged 45, was informed at another institution of the presence of premature systoles in 1939, but he was unaware of their presence. The diagnosis of syphilitic cardiovascular disease was made at that time and artsyphilitic treatment has since been administered. The Wassermann and Kahn reactions were 4 plus. The electrocardiogram revealed frequent ventricular premature beats from one focus, with fixed coupling, and a left ventricular preponderance.

The observations are illustrated in figure 6. The patient was seen on October 3 and February 26 and admitted to the hospital

direct evidence to suggest that this after-effect is the result of a cumulative action such as is found with digitalis.

That papaverine did diminish the frequency of the premature systoles is shown in the second period of observation. Here the incidence of premature beats was 16 per cent of the total beats in the control period, during papaverine treatment this was reduced to 4.5 per cent but returned to 29 per cent in the two days after papaverine was stopped.

On April 24 and 25 quinidine was tested and the results were compared with those of the control interval of the 22d and the 23d. The effect was striking and about equal to that of papaverine given on the 26th. A similar reduction of ectopic beats was found on the 29th with papaverine. The observations after the 23d were made primarily to note the hourly variations, these are illustrated in figure 6.

In this case, unlike the preceding ones, the ratio of premature to sinus beats is more variable. Nevertheless, the effect of papaverine is definite and convincing.

CASE 13—P B, a white man aged 40, had been rejected by several business firms since 1935 because of frequent premature beats. He was first seen at the Mandel Clinic in April 1940, at which time the electrocardiogram showed auricular premature systoles. He received quinidine by mouth (3 grains four times a day) but without appreciable results. His heart was normal on physical examination and in the teleroentgenogram. Blood pressure was normal and serologic examinations gave negative results, the electrocardiogram was normal except for the auricular premature beats.

The observations following administration of papaverine are shown in figure 7. Papaverine had a definite effect in the two trials, decreasing the frequency of the premature beats from 15 per cent, 13 per cent and 11 per cent of the total beats in the control intervals to 4.5 per cent and 4 per cent during the two periods of papaverine administration. The hourly distribution of readings is plotted on the right hand side of figure 7 during several papaverine, quinidine and control days. The effects of the papaverine and quinidine were about equal.

Comment—Our evidence demonstrates that papaverine administered orally in sufficiently large doses has a definite effect in abolishing or reducing the number of premature systoles of ventricular, nodal or auricular origin.

As a result of our experience we recommend a total dose of papaverine of from $4\frac{1}{2}$ to 21 grains (0.29 to 1.4 Gm.) a day, given four or five times at intervals of three to four hours. It may be taken before or after meals. The schedule may be varied according to the degree of abolition of the premature beats or according to the alleviation of symptoms, when present, arising from them. If symptoms occur at night and interfere with the patient's sleep, the last dose should be given before bedtime. A favorable result can be achieved with as little as $1\frac{1}{2}$ grains three times a day. In long term medication the aim should obviously be the use of the least quantity of papaverine required for an effect, since with larger doses the sedative action may become more prominent and even disturbing. One patient felt sleepy when receiving 3 grains five times a day, but this sensation promptly disappeared when the dosage was reduced. However, this hypnotic effect may be an advantage as, for example, in a patient with a myocardial infarct and premature systoles, or in patients requiring sedation for other reasons.

The results with oral papaverine in our series are comparable to those obtained with oral quinidine. We believe that papaverine is superior to quinidine, since we have not encountered any idiosyncrasy or the toxic symptoms occasionally caused by quinidine. Furthermore the former, unlike the latter, is not a myocardial depressant.⁹ The concomitant administration of papaverine and quinidine is feasible when the effacement or reduction of premature systoles is urgently indicated or when quinidine toxicity appears and requires stoppage of this drug.

Usually the effect of papaverine wears off within twenty-four hours after its discontinuance, but the intervals of papaverine medication in our cases were relatively short, and it is possible that with longer periods the abolition or diminution of the premature systoles might persist longer after cessation of the drug, as it was in 2 of our cases (cases 11 and 12).

Our experience with oral papaverine indicates that it is a useful and meritorious drug for the eradication or reduction in the number of premature systoles. It can be given over long periods, either therapeutically or prophylactically. It has particular utility in cases in which the premature beats produce troublesome symptoms and in those in which the condition is not par-

ticularly improved by quinidine. Its employment should be encouraged, especially in cases presenting clinical evidence of coronary insufficiency. Its lasting and strong coronary dilating action and its sedative effects are features that are desirable and supplemental. Abrogating or reducing the number of premature systoles may prevent one of the circumstances leading to anginal attacks and to the unwanted occurrence of paroxysmal rapid heart action. The latter is to be avoided, especially when of ventricular origin, for it is unnecessary to emphasize that one of the risks leading to sudden death in coronary disease is the occurrence of irreversible ventricular fibrillation. Any drug that will lessen the danger of this occurrence is obviously desirable. Our experiences with animals and the data on man presented in this report show that papaverine is such a drug.²⁵

SUMMARY AND CONCLUSIONS

1 The clinical report of the effect of papaverine on the anginal syndrome and on premature systoles presented here was initiated as a result of previous experimental studies on the dog's heart.

2 Oral papaverine in doses of $1\frac{1}{2}$ grains three or four times a day has proved highly successful in about 75 per cent of 17 intensively studied patients with the anginal syndrome.

3 Intravenously administered papaverine in doses of 1 to $1\frac{1}{2}$ grains causes a temporary abolition or reduction in the number of premature systoles, the effect lasting from two to ten minutes. It appears to be more successful in suppressing ventricular premature beats than auricular ones. For this purpose it may be given either in divided doses or in a continuous intravenous drip, diluted in saline or saline-dextrose solution.

4 Oral papaverine, in doses up to 3 grains four or five times a day had a decided effect in eradicating or reducing the frequency of premature auricular, nodal or ventricular systoles in 5 carefully studied patients. In this respect its favorable action is comparable to that of quinidine.

5 The oral administration of papaverine in heart disease is indicated in (1) the management of patients suffering from the anginal syndrome and (2) the eradication of premature beats. Its use intravenously is indicated for temporary abrogation or diminution of the frequency of premature systoles when these constitute a hazard (e.g. following a myocardial infarct) and for alleviation of a severe paroxysm of anginal pain. There is no contraindication to its use except possibly intravenously in complete auriculoventricular block.

6 Papaverine is superior to quinidine because 1 It is a potent and lasting coronary vasodilator. 2 It may be given intravenously in large doses with a wide margin of safety. 3 It has a mild sedative action. 4 It is not a myocardial depressant. 5 It does not cause the toxic signs sometimes resulting from quinidine.

7 The only toxic effects produced by papaverine are the occurrence of sleepiness when given orally in large amounts and the occurrence of transient intraventricular and auriculoventricular block, and occasionally transient ectopic rhythms previously absent, both lasting less than one minute, when it is given intravenously. Our experience convinces us that there is no evidence of any narcotic addiction from its use.

8 Papaverine should be employed in adequate doses, larger than those conventionally recommended.

Twenty-Ninth Street and Ellis Avenue

25 Recently relief of pain in acute myocardial infarction has been obtained from the intravenous use of papaverine 1 to $1\frac{1}{2}$ grains.

THE ROLE OF ARTIFICIAL INSEMINATION IN THE TREATMENT OF STERILITY

ALAN F. GUTTMACHER, M.D.
BALTIMORE

Artificial insemination or impregnation, as some term it, is one of those rare medical entities which cannot be traced back to Hippocrates. Furthermore, no reference exists to it among preliterate peoples.¹ In fact, its first human application was made only one hundred and fifty years ago.

According to the legend, the procedure was first evolved by fourteenth century Arabs in the breeding of horses. The legend specifically states that warring tribes stole into the enemy's camp and artificially inseminated well bred mares with the semen of inferior stallions—a practice without application in today's warfare of tanks.² In 1680 Jan Swammerdam, physician, mystic and natural philosopher of Leyden, reported unsuccessful attempts to fecundate artificially the eggs of fish, an experiment accomplished by Jacob in twenty years later. The success of the abbe Lazzaro Spallanzani in first artificially fertilizing an insect, then an amphibian and finally a dog is well known. After the intravaginal injection of semen the bitch was isolated in the abbe's own quarters and sixty-two days later brought forth 3 puppies all resembling the sire. Perhaps ten years later the illustrious John Hunter first succeeded in thus impregnating the wife of a linen draper on the Strand. The merchant was sterile because of hypospadias, and Hunter injected the husband's misdirected semen into the wife's vagina.² Normal pregnancy followed. J. Marion Sims in 1866 reported the first successful case in this country. Sims at first championed the procedure and later condemned both it and his own part in it on the ground that it was an immoral medical practice. Since 1907, the year that the Russian physiologist Iwanoff published his distinguished monograph on artificial insemination, it has played an increasingly important role in animal husbandry. Hundreds of horses, cattle, pigs and sheep are conceived by it each year in the Soviet Union. The Russian government has blooded males quartered throughout the agrarian regions in scores of animal breeding stations, and the peasants are encouraged to bring their mares, cows, ewes and sows for impregnation. In this way Russia improves the quality of the livestock, for by artificial insemination 1 blooded stallion may beget a half dozen or more colts at one service. According to Kersin, as many as 15,000 ewes were inseminated by 1 ram in the breeding season of 1936, and more than 1,000 cows by 1 bull. The average proportion of conceptions in the ewes was 96.6 per cent and in the cows 93.7 per cent.³ The Animal Husbandry Division of the United States Department of Agriculture, has become greatly interested in this topic and their seventy page circular written by Lambert and McKenzie is at once a scholarly and an amazing

survey of the theory and practice of artificial insemination in the horse, cow, sheep, pig, dog, fox, rabbit, chicken and turkey.³

Physicians to the human race, in comparison with physicians to dumb brutes, are leagues behind in both the scientific investigation and the successful practice of artificial insemination. To be sure, we are hampered by conventions, moral codes and frailties of human character, which never hinder the stockbreeder.

Three of the largest human series carried out by a single investigator are those of Schorohowa⁴ reported in 1927, of Cary¹ in 1940 and of Schultze⁵ in 1941. Schorohowa reports 50 cases with twenty-two successes. Cary 37 with fifteen pregnancies and Schultze one hundred and two attempts with fifteen successful. Schorohowa's report, the most optimistic, is far from convincing. The figures do not tally and there is a disturbing lack of detail in regard to such matters as the number of injections performed in each case. Furthermore half of his successful results appear to have followed injection during the most sterile phase of the cycle, within one to three days before an expected menses. Schultze's and Cary's papers, on the other hand, are quite detailed and accurate.

A consideration of the role of artificial insemination in the treatment of human sterility brings to the fore several matters for frank discussion. In the first place, when should artificial insemination be used? In the second place, what technique is to be followed? In the third place, what are its moral and legal aspects? Each topic is highly controversial.

INDICATIONS AND TECHNIQUE

The indications for artificial insemination may be divided into three main groups. In group A are those cases in which intravaginal coitus between 2 fertile individuals is impossible because of mechanical factors: impotence, hypospadias, vaginismus, tumors or excessive obesity. Group B is an all inclusive group made up of chronically sterile couples who finally qualify for this—the sterility treatment of last resort. Conditions admitting a couple to group B are legion, but I shall content myself in simply listing those printed in the three papers of Schorohowa, Schultze and Cary. They are ante flexed uterus with conical cervix, retroposed uterus with conical cervix, uncomplicated ante flexion, uncomplicated retro flexion, hypoplasia of the uterus, relaxed perineal body, salpingo oophoritis, endometritis, enlarged uterus, cervical abnormalities such as stenosis, endocervicitis and hypertrophy of the cervical mucous membrane, and a subnormal semen. In the third group, group C, are included only those cases in which the husband is sterile and the wife apparently fertile, or in which the husband has cacogenic hereditary characters which make a child sired by him ill advised. Schultze used artificial insemination in the treatment of 102 out of 2,000 sterility cases (5 per cent), while Schorohowa employed it fifty times in a series of 586 cases (9 per cent).

All physicians accept the value of artificial insemination in the treatment of groups A and C, that is when intravaginal coitus is impossible or when the semen of a fertile donor is substituted for the sterile or cacogenic semen of the husband.

From the Department of Obstetrics, Johns Hopkins University and Hospital.

I have had 2 patients in group A. The husbands were incapable of coitus but ejaculation of semen was possible by masturbation. In each, pregnancy occurred during the second course of intravaginal injections of the husband's semen. Cary, in his series of 37 artificial inseminations, had 1 case of hypospadias in which treatment was successful. Schultze had 48 couples for whom coitus was impossible. The women of all were treated by the intrauterine injection of the husband's semen and only 6 became pregnant. As I shall point out later, his low incidence of success in the A group may well have been that his patients received intrauterine injections while Cary's and mine were inseminated intracervically or intravaginally.

I have had 27 cases in group C which constitutes apparently fertile women who receive injections with semen collected from unrelated fertile donors. In 17 cases pregnancy resulted, 3 women are still under treatment and in 7 cases one or several treatments failed and further attempts have been discontinued. Cary reports 19 such cases with eleven pregnancies. If one eliminates the 3 cases which are under current treatment the combined figures from Cary's series and my own total 43 cases with twenty-eight pregnancies (65 per cent).

It seems pertinent at this point to say a word about artificial insemination with spermatozoa aspirated from the testicle by puncture of men whose epididymides or vasa deferentia are occluded. After Iwanoff had demonstrated the success of this procedure in the horse it was attempted in human cases. The testicles of the sterile husband are needled in several places, and after many punctures a few drops of secretion are aspirated. Two cc of sterile salt or Locke's solution is then sucked up into the syringe and mixed with the aspirated spermatozoa. The diluted spermatozoa are immediately injected into the wife at a favorable phase of her menstrual cycle. I myself have had no experience with the procedure. Schultze attempted it in 4 cases with failure in all. He states that no authentic successful case has yet been reported. Rohleder reported one pregnancy in a series of 7 patients but he himself suspected that the success may have been due to extramural activities on the part of the wife. Neither Young nor Cabot index this procedure in their textbooks of urology, and Himmelman dismisses the matter with the generality that "it has been tried successfully a few times."

Young, however, gives a detailed description of a somewhat similar procedure in his book on congenital abnormalities. He exposed the testicles, cut across distended tubules of the globus major, aspirated the spermatozoa and injected an estimated 200,000,000 into the uterus of the wife. This rather formidable procedure was done twice on the same patient without success. Young states that Hagner had also tried artificial insemination from aspiration of the epididymus and failed.

The B group is the group about which there is much difference of opinion with regard to the therapeutic value of artificial insemination. These are the cases in which no cause for infertility is found in either partner or at the most some nonsterilizing abnormality not directly concerned with the delivery or reception of the semen.

From purely the physiologic point of view, artificial insemination ordinarily has no advantage over coitus in treating sterility of undetermined origin, and I am convinced that it is also of little value in sterility due

to a subnormal semen. If the spermatozoa are so pathologic that they need "a 3 inch boost" on their 6 inch journey, I believe that they are likely to be sterile when face to face with a fertile egg.

I have performed intravaginal or intracervical inseminations in only 3 group B cases, a total of eighteen injections, with no success. In 2 the husband's semen was defective and in the other case both partners gave normal tests. Schultze employed artificial insemination with the husband's semen in 47 cases of this group. Twenty-eight women had hypoplasia of the uterus and 4 became pregnant but all aborted. Nineteen had cervical lesions and 3 became pregnant. Cary reports fourteen failures and three successes in this group—in 1 case the semen was subnormal and in 2 the women had acute antelexions. Together Schultze and Cary had 64 cases in group B with 10 pregnancies (16 per cent). It is important to point out that these authors performed intrauterine inseminations. If one is going to treat the problem of subnormal fertility by artificial insemination with the husband's semen I believe that intrauterine insemination offers greater likelihood of success than the intravaginal or intracervical method, since in reality these have been employed for years through normal coitus. On the other hand if artificial insemination is simply a substitute for coitus in instances in which it is physically or morally impossible, the intravaginal and intracervical routes are greatly superior.

Many authors make vaginal-cervical insemination absurdly complex. In group C cases that is in instances in which the semen of a fertile donor has been substituted for that of the sterile husband, I have had 72 per cent success despite the use of a very simple technic. Semen specimens are bought from medical students or staff members for \$5 each. The donor is selected because of racial and physical similarity to the sterile husband. Donors must be free from venereal disease and they must have a good genetic background and a highly normal sperm picture. The specimen is collected by masturbation into a dry, clean, wide necked bottle or drinking glass, no attempt being made to collect it sterily. There is no need for hurry. If the material is to be injected within two hours of ejaculation it may be kept at room temperature. If a longer period of time is to elapse, it is best kept in a corked bottle or test tube at 6 C.

The animal husbandry group has carried out some fascinating experiments on the effect of the age of the semen specimen on the success of artificial insemination. Walton and Prawochenski shipped ram semen from England to Poland and had successful impregnations twenty-seven hours after collection. Winters in this country reported two successful impregnations with ram semen that had been kept in the laboratory ice box for six days. Gunn reported as great a percentage of impregnations in ewes with semen stored for twenty-eight hours at 6 C as with fresh semen. The U. S. Department of Agriculture shipped bull semen to Argentina and had at least one successful impregnation. The time elapsed from collection to impregnation was seven days.³ As far as I know, similar experiments have not been carried out for man, and they would form an important investigative project for a research sterility clinic. Several of my successful results were accomplished with specimens 2 hours old.

The animal husbandry group has shown that the best place to deposit the semen varies with the species. In general it should follow the pattern of normal coitus.

For example in the cow it should be inserted 1 to 2 cm within the cervix, while in the sow it should be introduced directly into the uterus. The amount of semen necessary for successful artificial insemination also varies from species to species. In the chicken, for instance 0.1 cc is sufficient, while in the sow from 100 to 200 cc is necessary, depending on the size of the animal.³ Here again there are no similar scientific data for the human being.

The date for insemination is carefully selected on the basis of the menstrual data. If the cycle is twenty-eight days, the procedure in the first month is to select days 11 and 15 considering the day of the onset of the menses as day 1. If the treatment fails the first month, the next month days 10 and 14 are chosen, the next month days 12 and 16, and so on, varying the days back and forth within the confines of the fertile period. If the patient's average menstrual cycle is more than twenty-eight days, for example thirty-one I add the difference in days to the ordinary time for the first trial days 11 and 15. Thus with a thirty-one day cycle, I would begin on days 14 and 18. If the cycle were twenty-five days, I would subtract three, using days 8 and 12 for my first attempt. The watery, transparent character of the cervical mucus is helpful in delimiting the fertile days. Insemination is useless if the canal is exuding thick, viscid, opaque looking mucus.⁴

There is controversy in the literature regarding the value of coitus a few hours preceding artificial insemination in order to produce orgasm and thus perhaps increase the likelihood for ovulation. I have never suggested this to my patients and therefore know that preliminary coitus is not essential to success, and I doubt very much that it either favors or retards it.

All artificial inseminations are performed in my office, not in the hospital. I place the patient in the lithotomy position and elevate the hips slightly by cranking up the middle of the office table. A nonsterile, unlubricated bivalve speculum is inserted and the external os exposed. The blades of the speculum are relaxed so that the cervix just lies free between them. The semen is aspirated into a dry, nonsterile 2 cc glass syringe to which a metal, intravenous cannula is attached. Without either wiping away or displacing the mucus from the cervical canal the point of the cannula is introduced 0.5 to 1 cm within the external os and the semen spurted into the canal in four or five thrusts of the plunger of the syringe, simulating the pressure of ejaculation. As the speculum is withdrawn, the blade is wiped back and forth across the external os half a dozen times to bathe it in the seminal pool which has been formed by the semen running out of the cervix. A piece of absorbent cotton is placed superficially in the introitus to prevent soiling of the clothes with the semen. The end of the table is elevated, and the patient remains on her back with the legs extended in a comfortable position for twenty minutes, the hips still raised. She then gets up and goes about the day's routine. The patient should not have uterine cramps, and if she does it means that the cannula was inserted too high within the canal and some semen got into the uterus. After all, semen with its pungent hyperalkalinity acts distinctly as an irritating foreign body in the human uterus. Following coitus, the spermatozoa normally swim out of the semen deposited in the lower cervical canal and,

by the time they gain access to the uterus, have been washed free of the seminal plasma by the friendly cervical mucus.

Using this technic on 29 apparently fertile women, I have obtained 19 pregnancies. Three women are still being treated. The latter have had a total of nineteen inseminations with no success as yet. Seven have discontinued treatment after from one to ten inseminations, the total for the group being thirty-seven treatments. Four women in the successful group had a single insemination the month of impregnation, 11 had two treatments that month, 3 patients had three and 1 woman had four. The number of months required for success varied. Four patients became pregnant immediately the first month, eight the second month, two the third month, one the fourth month, three the fifth month and one after twenty-three months. The last was my first patient, on whom, from a lack of knowledge I was performing intrauterine insemination. Omitting this first case, the other 18 successful cases required a total of ninety-two inseminations, or an average of five and one-ninth per case. The equal effectiveness of artificial insemination and normal coitus is suggested by the following case.

A woman aged 31 whose husband, a teacher, was her first cousin had had two pregnancies each occurring the first month in which contraceptives were abandoned. The first pregnancy resulted in an premature fetus and the second in a spontaneous abortion showing defective germ plasma. In order to dilute the abnormal genes which were so tragically aimed through consanguinity they requested artificial insemination. This was done on the fourteenth and seventeenth days of her cycle, which varied from twenty-eight to thirty-five days. Despite a moderate cervical erosion, she became pregnant the very first month, exactly as she had done previously after coitus.

While doing intravaginal inseminations and inseminations into the lower part of the cervical canal, I have never stirred up or caused a single case of endocervicitis or salpingitis. If the donor is free of venereal disease, inseminations that do not invade the uterus are free of danger. In the 1 case in which I did intrauterine inseminations, my first case, a very mild, low grade inflammation of the right tube developed about forty-eight hours after a treatment. It subsided rapidly and has never recurred.

Among the successful inseminations there were a number of pathologic results—more likely due to a sampling error than to the way conception occurred. Among the fourteen deliveries there was one premature separation, one placenta previa, one ectopic pregnancy, one early abortion and one missed abortion, yielding a total of 10 healthy living children. Five patients remain undelivered.

As stated earlier, I have had little or no experience with intrauterine insemination. If used, it should be reserved for cases in which the husband's semen is injected, to compensate in some doubtful way for its inherent defects or to impregnate a wife who is refractory to ordinary impregnation for some mechanical reason. My skepticism of the value of artificial insemination in the treatment of ordinary sterility is overwhelming and it is difficult to keep an open mind.

Schulze⁵ goes into lengthy Teutonic detail about the technic of intrauterine insemination, and I shall condense his material. He insists that the inseminations be performed in a hospital. The donor in an adjacent room is provided with a dry sterile beaker wrapped in a sterile towel. He is also provided with a bell to announce the successful completion of his part in the

⁶ Guttmacher A. F. and Shettles L. B. Cyclic Changes in Cervical Mucus and Its Practical Importance. *Human Fertility* 5: 4 (Feb.) 1940.

procedure While the specimen is being obtained, the recipient is placed in the lithotomy position, and the vulva, vagina and cervix are prepared as for a vaginal operation A warm dry speculum exposes the cervix As soon as the semen is collected it is aspirated into a warm sterile syringe which is attached to a small catheter that has been inserted into the fundus Schultze then clamps the cervix to prevent a reflux of the semen into the vagina and slowly injects the whole ejaculate (from 1 to 3 cc) under very little pressure He then washes out the catheter by following the semen with 1 to 2 cc of warm sterile dextrose A little of the semen often gets into the tubes and sometimes even into the peritoneal cavity The catheter is then clamped off and strapped to the patient's thigh It is left in position for two hours and removed The patient is kept in the hospital overnight If uterine cramps are severe enough to disturb the stoic German hausfrau, a mild sedative is administered

Schultze warns of the danger of infection, which he claims is glossed over in many reports Franz has reported a case of fatal sepsis following the intrauterine technique

Schultze states that many authors prefer to inject only 1 or 2 drops of semen into the uterus, however, most German authorities prefer to use the whole amount

MORAL AND LEGAL ASPECTS

I should like to make a few remarks about the third problem, the moral and legal aspects Obviously all admit that there is no problem if the husband is the donor The following four rules, employed when an unrelated donor is used, are simply common sense rules Rule one, the donor must remain completely anonymous to the recipient and to the husband, and the recipient and the husband must remain equally anonymous to the donor Rule two, before artificial insemination is attempted the physician should know the couple, their intellectual capacity and their emotional stability and, if possible, the likelihood of a permanent marriage, only a small percentage of patients applying qualify for so radical a social procedure When a physician consents to do an artificial insemination from an unrelated donor, it is really the couple's insignia of good character Artificial insemination must never be an assembly line kind of medical treatment Rule three, never urge the procedure, and if either husband or wife is lukewarm drop it completely Rule four, make the fees low, keep artificial insemination out of the mercenary column View it as a personal medical service the contribution of an Aesculapian to the happiness of some wretched, worthy, sterile couple

The legal aspects of insemination from an unrelated donor are very complex and, according to the Bureau of Legal Medicine and Legislation of the American Medical Association, very precise and somewhat forbidding The attitude of the Bureau is well summarized in an editorial⁷ published in 1939 The law is the law, and those physicians who conduct their practices according to the primary law, which preceded all laws—"let your conscience be your guide"—are apparently in error For such men might wish to forego all signed papers and court proceedings in this procedure According to the Bureau, such an action would be highly irregular and "a great disservice, possibly an injustice in some cases, to the prospective child and may be depriving the child of rights of inheritance which the husband of the mother fully intends the child to possess

and would willingly safeguard if the actualities of the situation were made plain to him The law of legitimacy and the rights of a legitimate child as contrasted with a child of uncertain parentage are plain and all the wishful thinking will not alter the rights of the child if the incidents of its origin are revealed subsequently and if the rights of the child are not protected by adoption proceedings"⁸

A successful artificial insemination is one of the most satisfying of all medical experiences It would require a petrified heart not to warm to the scene of a sterile father doting on his two children, who, according to the neighbors, resemble him very closely

Clinical Notes, Suggestions and New Instruments

INTERMITTENT HYPOTHERMIA WITH DISABLING HYPERHIDROSIS

ARTHUR M. HOFFMAN, M.D. AND FREDERICK W. POBIRS, M.D.,
LOS ANGELES

In 1934 Hines and Bannick¹ described a clinical entity of recurrent hypothermia associated with disabling sweating It is the only case reported in the literature to date In 1935 we were privileged to observe a patient with apparently the identical condition We have studied him during approximately yearly attacks since that date and feel that the observations on this prolonged study and treatment are worth recording as the second instance in the literature

TABLE 1—Results of Tests

8 a m	0.94 cc
9 a m	0.98 cc
10 a m	0.97 cc
11 a m	0.99 cc
12 M	0.60 cc
1 p m	0.98 cc
2 p m	0.99 cc
3 p m	0.97 cc
4 p m	0.99 cc
5 p m	1.00 cc

Results are expressed in terms of N/50 acetic acid liberated from acetylcholine iodide solution in twenty minutes by 0.2 cc of laked blood

The normal range for human bloods so far as our studies go to date lies between a low of about 0.50 cc and a high of about 1 cc

The patient of Hines and Bannick, a man aged 22, was hospitalized because of intermittent attacks of sweating, chills and subnormal temperature He had had these attacks for ten years They would begin each year in December or January and would continue for from four to six weeks "At the onset of each attack there had been a period of nausea and vomiting of from five to seven days, following this gastric upset the usual cycles of sweats and chills had begun At intervals of approximately two hours there would be a cycle consisting of a drenching sweat, followed by a decided drop in body temperature, a chill lasting ten to thirty minutes, and a gradual return of the temperature to its previous level The patient was markedly exhausted and was completely disabled He had lost 12 pounds"

The patient was physically normal except for undernutrition, weakness and the episodes described Laboratory studies were normal except for low plasma chlorides Attempted control by atropine was unsuccessful, but oral replacement of salt improved the weakness, although not the attacks of hypothermia and chills On the assumption that sedation of the central

temperature regulating mechanism might control the bouts of low temperature, sodium amytal $\frac{1}{2}$ grain (0.032 Gm) was given every four hours. "This caused a striking change in the temperature curve and within eighteen hours the fluctuations ceased and the patient maintained a normal temperature of about 99°." For a control period the medication was discontinued with a return of the hypothermia, sweating and chills. Subsequently the patient remained in good control with sodium amytal and sodium chloride. Hines and Bannick postulated a localized encephalitis as the initiating factor in their patient's disorder but admitted that the long periods of remission between his yearly attacks were difficult to explain on this basis. However, they were not convinced that the patient was entirely normal between spells, and on close questioning the patient's mother admitted that he had been unusually sensitive to heat and cold, and she had not regarded him as quite a normal boy.

Our interest in the clinical picture described was first aroused in January 1935 with the appearance at the Santa Fe Coast

since 1909, he had not presented himself for medical attention prior to 1935 except for a blood count and basal metabolism in 1932 and 1934 because of fatigue. He was an only child with both parents living and well. He was married and his wife had arrested pulmonary tuberculosis. Their one child was healthy.

On physical examination the patient was alert, intelligent and cooperative. He was 5 feet 8 inches (173 cm) tall and weighed 130 pounds (59 Kg). In 1932, three years prior to this hospital admission, he had weighed 123 pounds (55.8 Kg) and in the interval had been as heavy as 136 pounds (61.7 Kg). The blood pressure was 130 systolic and 80 diastolic. No abnormalities were found on physical examination except during attacks of sweating, at which time he was cold, clammy and pale with beads of cold perspiration over the entire body sufficient to drench his pajamas. Roentgenograms of the chest were negative. A blood smear was negative for malarial parasites. Table 2 summarizes the laboratory findings from 1932

Chart 1—Temperature chart during hospitalization from Oct 30 to Nov 12 1915. 1 grain of amytal was administered every three hours.

Chart 2—Temperature chart during hospitalization from Oct 21 to Nov 5 1936. Administration of amytal was stopped from October 21 through October 26. One grain every three hours was administered from October 31 through November 5.

Lines Hospital of a man aged 43, a traveling freight agent for the Santa Fe Railroad, who complained of sweating, chills and weakness. An episode would consist of profuse sweating to the point of saturation of his pajamas about one hour after he would awaken early in the morning. His temperature would vary between 93 and 94.4 F. Within one to two hours a severe chill would occur, often lasting an hour. Following this, his temperature would rise to 98 F. within one to two hours. These attacks would recur each morning for from two to three months and had taken place usually each spring for ten years. One year he had his attack during the winter. In recent years the episodes had been more severe and he had been unable to work during them, but he would feel entirely well the remainder of the year. He had never had spells of nausea and vomiting at the onset of his attacks, as did Hines and Bannick's patient.

In his youth he had had measles, malaria and influenza. There had been no operations or accidents or other serious illness. Although he had been with the Santa Fe Railroad

to 1942. The charts present his temperature records in three of his hospital admissions in 1935, 1936 and 1937. They present graphically the effect of amytal on his hypothermia.

In 1936 roentgenograms of the teeth and of the skull were negative. In 1940 roentgen examination of the kidneys and urinary bladder was negative as was that of the lumbar and of the sacral spine. In 1935 a spinal tap revealed a clear, colorless fluid under normal pressure with 4 cells per cubic centimeter, globulin slightly increased, the Wassermann reaction negative and chlorides 702 mg per hundred cubic centimeters. Electrocardiograms taken Oct 22 and 26, 1936 in the midst of an attack revealed slight slurring of the QRS wave, low voltage of the T wave in lead 4 and left ventricular preponderance. On Jan 13, 1942 an electrocardiogram was identical to those of 1936. Because of the yearly recurrence of these episodes, so often in the spring, sensitization studies were made of sensitivity to pollens, foods, dust and feathers. These were all negative. The patient, moreover, gave an entirely negative allergic history.

He was hospitalized for study and treatment on three occasions—January to February 1935, October 1936 and November 1937. Each succeeding period of hospitalization was shorter than the preceding one as the patient's disturbance was controlled with amytal. From 1938 to December 1941 he had controlled four attacks by himself by promptly administering the drug at the first manifestation of hypothermia, sweating and chills.

In December 1941 he was admitted to the hospital because of pain in the right lower part of the abdomen of six hours duration. Laparotomy revealed acute appendicitis with early rupture. He had a hectic postoperative course with a temperature to 101 F for almost three weeks. Sulfanilamide had been administered in adequate concentration. Fluid developed in the right side of the chest which on aspiration was found to be clear, sterile and free from tubercle bacilli. He made an uneventful recovery. When his temperature had been normal five days he began to have early morning hypothermia to 95 F and on the third morning thereafter began to sweat and have chills as in his episodes of years past. Administration of amytal 1½ grains (0.1 Gm) during the night if awake or on early morning rising brought a prompt end to these bouts. Roentgenograms of the chest on discharge were negative. The patient has been quite well since his dismissal, Jan 6 1942.

COMMENT

In considering the possible pathogenesis of this patient's disorder, the similarity between his bouts and the sweating seen in the administration of acetylcholine was noted. Thirty mg of mecholyl chloride (acetylthetamethylcholine chloride) was therefore given subcutaneously. The degree of sweating produced was somewhat more pronounced than that seen in the usual patient to whom it might be administered. However, it had no pronounced effect on his temperature and was not followed by chills.

such determinations were made at hourly intervals from the time of the patient's awakening throughout the spell and for several hours thereafter (table 1). They must be interpreted as falling within normal limits.

Reimann² has discussed hypothermia seen in nervous persons and its relationship to neurocirculatory asthenia—a con-

Chart 3—Temperature chart during hospitalization from Oct 29 to Nov 8 1937. Spinal tap was done October 31 and 1 gram of phenobarbital given. From November 2 through November 8 1½ grains of amytal was given daily.

dition not uncommon and in contrast to the low grade fevers presumably of neurogenic origin frequently seen. In none of Reimann's case reports, however, was there the degree of hypothermia as seen in our patient and that of Hines and Bannick's nor did excessive sweating, chills or disabling weakness accompany the hypothermia.

This clinical picture as first described by Hines and Bannick and now supplemented herewith by us seems a distinct and unusual entity. We have reported our seven year observations and studies in detail in the hope that other observers may be able to shed light on its frequency and pathogenesis.

SUMMARY

The case here reported is the second instance of an unusual and apparently distinct clinical entity consisting of yearly bouts of hypothermia with disabling sweating. Attacks occur about once a year and last for two or three months if uninterrupted by therapy. Each daily attack consists of early morning hypothermia usually 93 to 94.4 F, followed in an hour by profound

TABLE 2—Summary of Physical Examinations (1932-1941)

	1932	1934	1935	1936	1937	1941

Blood pressure		138/80	100/70	104/86	122/70	143/90
Weight	123			134		

Acetylcholine is widely distributed in the body and presumably is released at nerve endings with each nerve impulse. It however cannot be measured in the tissue or body fluids. It is rapidly inactivated in the tissues by an enzyme, cholinesterase which is amenable to quantitative measurement in the body. The theory that a deficiency in cholinesterase might allow for greater acetylcholine activity in our patient and so account for his peculiar episodes seemed intriguing. Through the cooperation of Dr. Gordon A. Alles and Roland C. Hawes

drenching hyperhidrosis. Within an hour chills occur, after which the temperature gradually rises to normal. During the periods of bouts the patient is disabled. Administration of amytal as a central nervous system depressant on the temperature regulating center prevents the recurrence of attacks.

WINGED SCAPULA CASE OCCURRING IN SOLDIER
FROM KNAPSACK

FREDERIC W ILFELD M D

Captain M C U S Army Chief of Orthopedic Section,
Station Hospital

AND

HALL G HOLDER M D

Lieutenant Colonel M C U S Army Chief of Surgical Service,
Station Hospital

CAMP CALLAN CALIFORNIA

Prominence or winging of the scapula was described in 1825 by Velpeau, who attributed this deformity to paralysis of the serratus anterior muscle.¹ Since that time cases of this type have been reported due to poliomyelitis, birth palsy, postinfluenzal neuritis, diphtheria, erysipelas, cerebral palsy and progressive muscular dystrophy.² Ball³ has reported 1 case of paralysis

Fig 1—Winged right scapula condition on admission to hospital

of the serratus anterior in a midshipman following an injection of antitetanic serum, and McGoogan⁴ reported 3 cases occurring during the puerperium. Such trauma as the following may cause the same deformity: swinging at a punching bag and missing, being kicked by a horse, pulling energetically on a hand clutch, golfing, using crutches, pressure from a cast, the postural habit of sleeping on the outstretched arm,⁵ following an abdominal operation,⁶ carrying weights on the shoulder and a direct fall.¹ Search of the literature on this subject fails to reveal

mention of winging of the scapula from carrying a knapsack. In view of the expansion of our armed forces during the present emergency, the occurrence of this deformity from such cause, its recognition and its treatment are important.

L F L, a private in Company B of the 51st Anti Aircraft Training Battalion, Coast Artillery, Camp Callan, was admitted to the Station Hospital on Sept 4, 1941 complaining of difficulty in raising the right arm and of prominence of the right scapula. One week previously while carrying a fully loaded knapsack on a hike he noticed, after the first rest period, a numbness of the right arm. The following day on sitting down the right shoulder blade seemed to "strike the back of the chair." The patient thought that the first symptoms were possibly due to having strained the right shoulder while putting his pack on his back. There was no other history of trauma to the shoulder and there was no exposure to cold or dampness. The patient had always been well and strong and had suffered from no serious illnesses in the past. There was no history of familial disease and no history of poliomyelitis. The general physical examination was within normal limits. When the right arm was raised in flexion or abduction the right scapula was prominent (fig. 1) the vertebral border being about 4 inches from the spinous processes and displaced backward about 1 1/2 inches. Active abduction was possible to 160 degrees, flexion to 160 degrees, internal rotation with the arm at the side to 70 degrees and external rotation to 65 degrees. A complete muscle examination revealed a weakness of the serratus anterior muscle. All other muscles rated normal according to Legg's method of muscle testing. The knee and ankle jerks were present and equal. The Kahn test was negative, and urinalysis was within normal limits.

The weakness of the serratus anterior muscle in this instance was probably due to stretching of the long thoracic nerve in swinging the pack on the back or to pressure on the long

Fig 2—Condition four weeks later

thoracic nerve from the strap of the knapsack against the chest and shoulder. Treatment consisted in support to the arm with a sling, infra-red heat and massage to the shoulder. At the end of one week there was a slight improvement in the muscle power of the serratus anterior. Gradual improvement continued, a check up examination on September 26, about

four weeks after the initial onset of symptoms, showed no evidence of winging of the scapula or any weakness of the serratus anterior (fig 2)

Various forms of treatment for this deformity have been used in the past. Fitchet² advises immobilization and support of the muscle with an airplane splint, Horwitz and Toernatus¹ use a brace elevating the elbow, McGoogan⁴ believes that vitamin B therapy is indicated. Ball's³ patient recovered following the application of galvanic and sinusoidal current. Berkheiser and Shapiro⁷ used a plaster spica holding the arm in abduction and external rotation. More recently Foley and Wolf⁸ have designed a special brace to relieve the strain on the serratus anterior. For the correction of permanent and disabling deformity the following operations have been devised: anchoring the vertebral border of the scapula to the spinous processes of the fourth to seventh cervical muscles, fixation of the vertebral border of the scapula to the opposite ribs, implantation of the subscapular nerve to the paralyzed serratus muscle and suturing of the middle portion of the pectoral muscle to the angle of the scapula.⁹

GAINS AGAINST EPILEPSY

CLINICAL LECTURE AT ATLANTIC CITY SESSION

WILLIAM G. LENNOX, M.D.

BOSTON

A new day—long overdue—is dawning for persons with epilepsy. The ungodly length of the night which has enveloped both patients and physicians is disclosed by a backward glance. If plotted as a curve, medical knowledge about epilepsy would have an initial high point at the time of Hippocrates, followed by a decline to a long, flat level which persisted for two thousand years. About 1700 began a wavering rise. In the last eighty years sharp ascents have coincided with the working lives of Hughlings Jackson, of Gowers and of Hans Berger. Unfortunately a curve representing improved medical treatment lags far behind the rising curve of knowledge. When man lost faith in demons as a cause of seizures, mistreatment by scourgings and trephinnings became less popular but no effective positive therapy was substituted. Neither Juhus Caesar, Mahomet, nor Lord Byron could purchase any medicine which would influence fits. The years 1857 (bromides), 1912 (phenobarbital) and 1938 (diphenyl hydantoin) mark precipitous therapeutic advances and surges of new hope in successive generations of epileptic persons.

So rapid has been the increase of knowledge in the last decade that many practitioners of medicine and their patients have been left far behind. So broad has been the advance that any adequate discussion would deal with many subjects: psychology, psychiatry, cerebral circulation and the anatomy, pathology, surgery, physiology, physics and chemistry of the brain. The rest of the body cannot be neglected, for the brain is a constitutional monarch and its actions are influenced by the activity of endocrine glands by the metabolism

of body tissues and by the state of the emotions. Furthermore, epilepsy presents social and economic as well as medical problems. The present war will increase the burden of epilepsy. The lives of the epileptic are not being risked either in fighting or in industry, and inevitable war injuries will greatly increase the present army of half a million persons who are subject to convulsive seizures.

Knowledge of epilepsy has advanced on an uneven front. In the last few years brilliant gains have been scored by neurosurgery.¹ I shall speak only of the advances made in three fields in which my associates and I have been especially interested—electroencephalography, heredity and drug therapy.

ELECTRICAL PULSATIONS OF THE BRAIN

More than almost any other vital organ, the brain is protected from the inquiring eye and hand of the physician. Diseases of the brain, such as epilepsy, have for many centuries been considered inscrutable and incurable. Dramatically, demonstration that the electrical activity of the brain can be recorded and can be correlated with certain abnormalities of mind or conduct has caused a reorientation and clarification of ideas regarding many of the age old questions about epilepsy. Admittedly, study of the electrical pulsations of the brain, though answering many immediate questions, uncovers new and deeper ones. Admittedly, little is known about the ultimate origin of brain waves but this ignorance does not prevent productive use of the technic called "electroencephalography." We do not refuse to use the telephone until the nature of electricity is fully understood.

Study of the electrical potentials of the brain has resulted in knowledge of both theoretical and practical value. Electroencephalography demonstrates what Hippocrates suggested, that the seat of seizures is in the brain and not, as some moderns imply, in the intestine, the endocrine glands or the id. In patients having localized or jacksonian convulsions the disordered brain waves arise from one area, but in most patients the disturbance is widely diffused over the cortex. During each of the various types of seizures, petit mal, grand mal and psychic, the form of the electrical pattern is distinctive. The illness of the patient is not confined to the rare periods of seizures, but some degree of cortical dysrhythmia is discernible in nine tenths of patients during a fifteen minute period of observation. Other disorders of the nerves or of conduct not generally identified with epilepsy also have disturbances of brain rhythm. Of children with "behavior problems," inmates of prison, the victims of migraine or of schizophrenia, a third or more have disordered brain rhythms. Detailed treatment of this subject of electroencephalography is in the Gibbs atlas.²

Beneath the flimsy borderlines of diagnosis based on symptoms lie the more fundamental physiologic classifications based on the electrical activity of the brain. New possibilities of treatment are opened by these observations. Seventy years ago Maudsley³ contended that many sudden storms of temper or of peculiar or anti-social action were akin to seizures of epilepsy and should receive hospital and not prison treatment. In a number of patients we have been able to demonstrate the truth of Maudsley's contention. Persons such as he described

have had brain waves similar to the waves of patients suffering from psychomotor epilepsy.

However, doubt may be cast on the serious implications of dysrhythmia by the fact that a disturbed rhythm is present in many persons who have never displayed any peculiarities of mind or conduct. Among 1,000 unselected persons composing so-called normal groups of adults—such as college and medical students, nurses and draftees—Dr and Mrs Gibbs⁴ found that some peculiarity of brain rhythm was present in 16 per cent and gross dysrhythmia in 2 per cent. Undoubtedly some of these persons had suffered brain injury or had symptoms which could be correlated with the dysrhythmia, but for the majority no such explanation is at hand. Possibly genius or unusual qualities of personality or mind may later be correlated with brain wave patterns which are now termed abnormal. More serious is the question "May normal persons with abnormal brain waves be persons who are themselves predisposed to epilepsy or an allied disorder or are 'carriers' of a tendency which may appear in an offspring?"

Fig 1—Electroencephalographic tracings of three normal identical twins aged respectively 22, 39 and 61 years. Tracings of the first two twins are grossly abnormal and of the third are a trifle slow. The tracings are five second samples taken from a record of fifteen minutes duration. In each instance simultaneous records were made from six different areas of the skull but a tracing from only one region is reproduced. For the 3 twins the regions used were respectively left occiput (L O), right motor (R M) and left motor (L M). The perpendicular line at the right indicates the signal made by 50 microvolts; the horizontal line at the bottom marks the time of one second. Tracings are reduced one half.

HEREDITY OF BRAIN WAVES AND EPILEPSY

The doctor is asked no more insistent or difficult question than this "Should I an epileptic, or the relative of an epileptic marry and have children?" The confusion of professional opinion is illustrated by the fact that this question when appearing in *Queries and Minor Notes* in *THE JOURNAL* has brought answers which were exactly opposite.

Certain stock answers built from statistical data can be given to inquiring patients. Epilepsy occurs in about 28 per cent of the near relatives of noninstitutional patients, or five times more frequently than in the general population. However, the chances of having epileptic offspring are lessened by various circumstances: if the patient has no family history of epilepsy or migraine; if he was mentally normal at birth; if his

seizures began late, if a history of brain injury antedated the first seizure, and above all if he marries a person who carries no predisposition to seizures. These criteria are of presumptive value, but those who are most interested want an individual and not a general answer. Of what help is the electroencephalograph?

Obviously, to the insistent question about heredity the pulsations of the brain can give no answer if these pulsations are the result of environmental conditions. Therefore we must first answer these questions: Is the pattern of the electrical waves of the brain a constitutional or an acquired characteristic? Is the electrical pattern traced by the brain comparable to a person's facial expression which is altered by emotions, by injury or by cosmetics or is it like his features, his eyes and nose and ears which resemble those of parents or grandparents and change but little through the years?

The heredity of identical twins is the same, therefore in these twins characteristics which are due to heredity are identical, whereas those due to environment are different. If the pattern of brain waves is a hereditary trait, then brain waves of identical twins, which have the same heredity, should be the same, whereas the brain waves of nonidentical twins should be different. Dr and Mrs Gibbs and I⁵ have made records of 65 nonepileptic twins, none of whom had suffered brain injury. Fifty-two twins were believed to be monozygotic and 13 were dizygotic. Without knowing to which class the paired electroencephalographic records belonged, Mrs Gibbs inspected the records and decided which pairs of tracings were identical and which were different. In 5 per cent her decision was in error, in 8 per cent she was in doubt and in 87 per cent her judgment was in agreement with the physical criteria of identity. Illustrative tracings of three adult twins are shown in figure 1. The similarity of records of identical twins was especially obvious if the brain waves were abnormal in frequency or in voltage. These observations confirm the study of nine identical normal twins made by the Davises.⁶ If records are made under standard conditions and recognition is given to the fact that brain waves are a fluid not a fixed trait we believe that the pattern traced by the electrical pulsations of the brain is a hereditary trait. The electroencephalogram may be used together with measurements of height, weight and the color of eyes and hair in decisions involving the identity of twins.

This point settled, we then analyzed the electrical records of twins, 1 or both of which had a history of seizures. In this series of 20 twins there were 12 identical twins, only 1 of which was subject to seizures at the time of examination. In each of these 12 twins the brain wave records of the epileptic twin and of his nonepileptic co-twin were alike with respect to being normal or abnormal and with respect to the underlying dominant rhythm. However, if the epileptic member had suffered brain injury or if his seizures had been present for many years, his brain wave record presented abnormalities not found in the record of his normal twin. In 2 of these twins the normal co-twin had a history of one or two convulsions at the time of an infection in childhood. In 3 other twins the normal co-twin has had a seizure since the electrical examination was made. In the remaining 7 twins only 1 member has ever had a seizure.

Of these 7 identical twins, 2 proved to be non-epileptic. The seizures present in the first twin were purely symptomatic. This child had received a head injury, following which she had two convulsions, and electrical records showed cortical dysrhythmia. Several months later the brain waves had returned to a normal pattern which was indistinguishable from that of her uninjured co-twin. In the second twins both the patient and his normal brother had normal and identical brain waves. The patient's seizures proved to be hysterical. There remained 5 identical twins who gave a history of chronic epilepsy in 1 twin and no seizures in his co-twin. Instances of this sort have been advanced as substantial evidence against the importance of heredity in epilepsy. In each of these 5 twins the record of the normal twin as well as that of his epileptic co-twin was grossly abnormal. In each instance also the epileptic twin had a history of injury to the brain which antedated his epilepsy. As a result of these observations of twins affected by epilepsy, we believe that essential epilepsy develops on the basis of a pre-existing cerebral dysrhythmia. Each of the identical twins had a predisposition as evidenced by dysrhythmia, but the brain of the epileptic twin received some injury or underwent some physiologic upset which caused the dysrhythmia to be expressed in overt seizures.

We extended the investigation by making electrical records of other members of the immediate family of epileptic patients.⁸ Of the 312 relatives examined so far, brain waves were judged to be abnormal in 52 per cent. Corresponding values are 16 per cent for adult normals and 85 for adult epileptics. Both parents of 88 patients were examined. In 27 per cent of these families both parents had abnormal records, and in only 8 per cent were the records of both clearly normal. Other workers have furnished corroborative evidence.⁹

Leaving the sea of brain waves and statistics, what can we conclude about the heredity of epilepsy? We can confirm the opinions which clear-minded clinicians have been expressing for many decades. Epilepsy per se is not inherited, but a "predisposition" or "tendency" may be inherited. A predisposition (heredity) lies dormant until activated by injury or serious disturbance of the brain (environment). Both seed and soil are needed for the growth of epilepsy. Both spark and gunpowder are required for the explosion of a fit. This is exactly what clinicians have said for decades about many other illnesses which beset mankind, diabetes, obesity, hypertension and what not.

The evidence which we have collected suggests that an abnormal brain wave pattern which is constitutional and not acquired may indicate a predisposition to epilepsy or some other disorder associated with cerebral dysrhythmia. If this suggestion is confirmed by more extensive study, we may advise epileptic patients and their relatives about children on the basis not of general statistics but of actual observation of the brain wave pattern of those who are married or propose marriage. In arriving at a conclusion, several points deserve emphasis: first, the need for taking into consideration other inheritable and valuable traits which may outweigh the presumably undesirable trait of dysrhythmia; second, the importance of securing a record of the sup-

posedly normal partner, and, third, the need for determining the significance of the degree of abnormality or of the specific pattern of a given brain wave record. This last point is a matter for further research. Dr and Mrs Gibbs have divided electroencephalographic records into eighteen different groups. They have compared the distribution of these eighteen classes of records in three groups of persons: 1,000 adult "normal" controls, 129 adult relatives of epileptic patients and 628 adult epileptic patients. Records were counted as abnormal if the dominant frequency of waves of normal or high voltage was outside the range of 8.5 to 12 per second. Records with dominant frequencies which were very slow or very fast or records which showed paroxysmal discharges of high voltage slow or fast waves, so-called "seizure discharges," may be called "grossly abnormal." Very slow or very fast records constituted 7 per cent of the abnormal records in the control group, 11 per cent in the group of relatives and

Fig. 2—A schematic representation of some of the etiologic factors and the mechanism of epilepsy. The large circle at the bottom represents a germ cell containing many large protein molecules which are the genes of various traits. The gene at the left comes to be represented in the neuron the discharging cell of the brain. This representation is either an abnormal chemical structure of the neuron or an abnormal reaction to stimuli. This abnormal quality results in discharges which are improperly regulated as to rate and voltage as shown in the electroencephalogram. Three types of asymptomatic dysrhythmia are portrayed: slow (psychic), fast (grand mal), and alternate slow and fast (petit mal). At the top of the chart appear the symptoms which result from the dysrhythmia. There is some as yet not understood externalizing mechanism which makes an asymptomatic dysrhythmia into one which is symptomatic. In addition to the three classic types of seizures there may be allied disorders of personality of behavior of mentality and possibly of genius. All this so far represents idiopathic epilepsy. At the lower left hand corner of the chart is a neuron which arises from a germ cell which did not contain the gene of dysrhythmia. If however this normal cell is injured, dysrhythmia, both asymptomatic and symptomatic may result. This combination represents the so-called symptomatic epilepsy.

24 per cent in epileptic patients. Records with "seizure discharges" formed 5 per cent, 13 per cent and 37 per cent of the abnormal records in these three groups. This evidence suggests that grossly abnormal brain waves and especially the patterns which most commonly appear in the records of patients with epilepsy carry a darker hereditary implication than brain waves which differ but moderately from the norm.

Both in the population which is closely related to the epileptic and in the general population, persons with dysrhythmia outnumber those who are subject to seiz-

ures twenty times or more. Just as Pearl Harbor silenced the phrase "This is not our war," electroencephalography brings the problem of epilepsy and related disorders before not merely the half million persons in this country who are subject to seizures but also before the millions of persons who have abnormal patterns of brain wave activity. Questions of marriage and children apply not only to persons with seizures but to the very much larger group who may be capable of transmitting the dysrhythmia and the predisposition. The whole problem is greatly enlarged and complicated by the fact that, as indicated earlier, epilepsy is not the only disorder associated with cerebral dysrhythmia. The local war against epilepsy has become a global war against cerebral dysrhythmia and all it represents. This is not a discouraging prospect but one turgid with hope.

Eugenics is given a new weapon, the opportunity to deal not simply with the few victims of a certain disorder but the twenty times more numerous "carriers" of the disorder. Individual prophylaxis has a new meaning, for possibly the enemy's invasion bases can be destroyed, possibly disordered brain waves can be corrected before symptoms have an opportunity to appear.

The word "heredity" connotes the inevitable and the unalterable. Even if this were so, in the case of dysrhythmia the accessory acquired conditions, such as brain injuries, may be prevented and epilepsy never appear. But heredity, represented by dysrhythmia, is a fluid characteristic, modifiable by chemical means. This fact gives new impetus to studies of the chemistry of the brain in relationship to dysrhythmia and seizures. Certain types of dysrhythmia can be temporarily abolished by intellectual activity, by the use of anticonvulsant drugs or by altering the carbon dioxide or sugar content of the cerebral blood. Occasionally prolonged use of anticonvulsant medication will improve a patient's record.

By means of blood samples drawn simultaneously from an internal jugular vein and from an artery, the metabolism of the brain can be studied while its electrical activity is being recorded. Substantial observations have been made which are too detailed to be recited here. A conception of some of the important etiologic aspects of epilepsy is portrayed in figure 2. Areas of most strategic importance for the clinician are two: first, the peculiar chemistry or metabolism of the discharging neurons of the brain which causes dysrhythmia of the brain, and, second, the conditions which cause this dysrhythmia to become externalized in a fit. These two areas have been brought into focus by the use of effective anticonvulsants.

PHENYTOIN SODIUM

Perhaps the most immediately acceptable of all our lately acquired knowledge is a new and better drug for the control of seizures. Putnam and Merritt believed that continued search might disclose a more effective drug than bromide or phenobarbital, drugs whose effectiveness was discovered by chance. Sodium diphenyl hydantoinate, whose official name is phenytoin sodium and trade name Dilantin Sodium, is the result of their search. Presumably the award of an even more effective anticonvulsant awaits other workers with equal faith and persistence. Already phenytoin sodium is recognized as the drug of choice for patients having grand mal or psychomotor seizures. Its usefulness should not be lessened just because its administration requires careful and intelligent supervision by the

attending physician. Ignorance or timidity on the part of the doctor has blighted the budding hope of many a patient. Different writers have reported various degrees of success in the use of this new drug. To mention only the earliest and the latest reports, in treating 267 patients Merritt and Putnam¹⁰ were able to secure satisfactory results in more than two thirds, whereas Finkelman and Arieff,¹¹ treating 41 patients, obtained continued benefit for only one sixth. If patients are unselected, widely differing results presumably reflect varying degrees of professional experience and skill. Epilepsy is a tough disease which laughs at dull weapons. Phenytoin sodium is a sharp edged weapon which must be used both boldly and deftly.

I myself have never encountered a patient who had suffered lasting hurt from phenytoin sodium, but I have seen a number who reported no benefit from use of the drug but whose seizures stopped when the dosage was increased to the threshold of tolerance. Success can never be attained by giving a fixed amount of medicine to each patient. Usually doctors err on the side of caution. As with the digitalization of a cardiac patient minor toxic symptoms are to be expected. In severe cases of epilepsy the amount taken daily, 0.3 to 0.6 Gm. ($4\frac{1}{2}$ to 9 grains) should be the amount which either will control seizures or is just below the level at which unpleasant symptoms, such as dizziness, muscular incoordination, gastric distress, severe swelling of the gums, excessive activity or loss of weight appear. Incoordination is by far the most frequent symptom. None of the common early symptoms are serious, and the alert physician will not permit his patients to develop symptoms which are serious. Finally, the doctor of the future will treat dysrhythmia before epilepsy begins or will continue to treat it after seizures have disappeared.

The success of phenytoin sodium, which is not hypnotic and which is most effective in certain types of cerebral dysrhythmia, opens a new field for investigation. The opportunities for chemotherapy would seem to be as great in the area of cerebral dysfunction as they have proved to be in the area of bacterial infections.

THE DIFFUSION OF KNOWLEDGE

More complete knowledge of the cause and treatment of epilepsy can and should be secured, but of what use is knowledge which is sealed in laboratories or in the consulting offices of high fee specialists? The Laymen's League Against Epilepsy has been organized for the encouragement of research and the education of the public. One agency of education is a book about epilepsy written for both doctors and intelligent laymen.¹² However, on the family friend, the practitioner of medicine, rests the principal burden of bringing hope and health to a large group of patients now sadly neglected.

SUMMARY

In the last ten years remarkable progress has been made in the understanding and in the treatment of epilepsy. Study of the electrical pulsations of the brain have been particularly rewarding in diagnosis, in the localization of cortical lesions and in giving advice regarding marriage and children.

The obscure ancient terms "idiopathic" and "symptomatic" epilepsy should be replaced by the clearer modern terms 'genetic' and 'acquired' epilepsy. The brain wave pattern is believed to be a hereditary trait. Epilepsy is not inherited but a predisposition to epilepsy or allied disorders may possibly be evidenced by a hereditary cortical dysrhythmia. Dysrhythmia, however, is not a fixed trait but may be modified and perhaps corrected by chemical means. This possibility is enhanced by the beneficial effects observed from the use of the non-sedative drug phenytoin sodium.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN I. SMITH, M.D., Acting Secretary

CYCLOPROPANE (See the Revised Supplement to N. N. R. 1941, p. 11)

The following product has been accepted:

E. R. Squibb & Sons, New York

Cyclopropane 30 gallon, 75 gallon and 200 gallon cylinders, 2 gallon, 6 gallon and 25 gallon Ampoules

BARBITAL SODIUM (See New and Nonofficial Remedies 1941, p. 128)

The following dosage form has been accepted:

SCHERING & GILATZ, INC., New York

Elixir Medinal 6 ounce and 1 gallon bottles. A solution containing in each 4 cc (1 teaspoon), 0.12 Gm (2 grains) Medinal in 20% alcohol

NIKETHAMIDE (See THE JOURNAL, March 28, 1942, p. 1052)

The following dosage forms have been accepted:

GEORGE A. BREON & CO., INC., KANSAS CITY, MO

Solution Nikethamide 25% W/V 0.375 Gm, 1½ cc ampul, and 0.25 Gm, 3 ounce, 15 cc and 1 pint bottles for oral use

SULFADIAZINE (See THE JOURNAL, Feb. 28, 1942, p. 730)

The following brand has been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Sulfadiazine (Powder) bulk

Tablets Sulfadiazine 0.5 Gm (77 grains)

SULFADIAZINE (See THE JOURNAL, Feb. 28, 1942, p. 730)

The following dosage form has been accepted:

SHARP & DOHME, INC., PHILADELPHIA

Tablets Sulfadiazine 0.5 Gm

SODIUM SULFADIAZINE (See THE JOURNAL, July 4, 1942, p. 794)

The following dosage form has been accepted:

SHARP & DOHME, INC., PHILADELPHIA

Sodium Sulfadiazine (Sterile Powder) 5 Gm vials

SULFATHIAZOLE (See New and Nonofficial Remedies, 1941, p. 514)

The following dosage form has been accepted:

FREDERICK STEARNS & COMPANY, DETROIT

Tablets Sulfathiazole 0.5 Gm (7716 grains)

PHENOBARBITAL (See New and Nonofficial Remedies 1941, p. 141)

The following dosage forms have been accepted:

GEORGE A. BREON & CO., INC., KANSAS CITY, MO

Tablets Phenobarbital ½ grain and 1½ grains

Council on Foods and Nutrition

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

FRANKLIN C. BING, Secretary

FRUIT JUICES INCLUDING TOMATO JUICE (See Accepted Foods, 1939, p. 49)

Mission Dry Corporation, Los Angeles

MISSION BRAND CONCENTRATED CALIFORNIA ORANGE JUICE an unpasteurized orange juice concentrate formed by evaporating California Valencia Orange Juice under reduced pressure to approximately 15 per cent of its original volume. Because this product receives no heat treatment it is distributed only to institutions in which it can be properly refrigerated.

Analysis (submitted by manufacturer)—Moisture 35% total solids 65% ash 2% fat (ether extract) 0.6% protein (N × 6.25) 4.6% crude fiber 0.2% available carbohydrate 48.4% total solids as citric acid 5.3%

Calories—2.6 per gram 78 per ounce

Vitamin Claims—Ascorbic acid (determined by 2,6-dichlorophenolindophenol titration) 293 mg per hundred cubic centimeters. When diluted with 5.75 volumes of water as recommended the resulting drink contains 44 mg of ascorbic acid per hundred cubic centimeters which closely approximates the reported values for fresh orange juice.

MILK AND MILK PRODUCTS OTHER THAN BUTTER (See Accepted Foods, 1939, p. 230)

SOFT CURD MILK PRODUCED BY TREATMENT WITH PROTEOLYTIC ENZYMES

It has been shown that milk which has been subjected for short periods of time to the action of proteolytic enzymes retains the physical properties of ordinary milk but uniformly produces a soft curd.¹ This effect has been attributed to a mild hydrolysis of the proteins of milk, a hydrolysis so mild that it can scarcely be detected by the chemical estimation of free amino groups. Turner found only slight increases in free amino groups as determined by the Van Slyke method but reported a significant increase in the alcohol soluble protein and some increase in the proteose peptone fraction.² This investigator has also shown that there may be a slight increase in the rate of digestion in vitro of the proteins of enzyme treated milk over the proteins of ordinary pasteurized milk.

ENZYLAC MILK

Enzylac Powder, manufactured by The Armour Laboratories, Armour and Company, Chicago, is distributed by the American Seal-Kap Corporation, Long Island City, N. Y., to dairies desiring to use this process of producing soft curd milk, is manufactured under U. S. Patent Number 2115505 and consists of a trypsin preparation derived from defatted pancreatic glands of hogs and cattle. Twelve and six-tenths Gm of the commercial Enzylac Powder is mixed with 100 gallons of cold milk, which with constant agitation is raised to a temperature of 100 to 120 F for not more than fifteen minutes. The milk is then pasteurized, cooled, packaged in the usual manner and marketed under the name of Enzylac Milk.

Individual brands of pasteurized Enzylac Milk, with or without added vitamin D, are given consideration by the Council with a view to acceptance provided the submission of such products is accompanied by signed reports of curd tension tests. Claims for accepted products may not exceed the allowable claims for soft curd milks made by other methods³ and must otherwise conform with the Rules and Decisions of the Council.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156)

Harold H. Clapp, Inc., Rochester, N. Y.

CLAPP'S CEREAL FOOD FOR BABIES, a flaked dried cooked mixture of ground whole wheat, degerminated corn meal, wheat germ, malt, dried skim milk, dried brewers' yeast, dicalcium phosphate, sodium chloride and iron ammonium citrate, U. S. P.

Analysis (submitted by manufacturer)—Carbohydrate 71.7% protein (N × 6.25) 16.0% fat (ether extract) 1.2% ash (total minerals) 3.8% crude fiber 1.6% moisture 5.7% calcium (Ca) 0.34%, phosphorus (P) 0.80%, iron (Fe) 0.021%, copper (Cu) 0.002%.

Calories—3.43 per gram 97 per ounce

Vitamin Claims—According to the report of biologic assay (1941) submitted by the manufacturer the product contains 0.01 mg of thiamine per gram, 0.3 mg per ounce and 0.002 mg of riboflavin per gram, 0.07 per ounce.

SATURDAY, OCTOBER 10, 1942

UTILIZATION OF CARBON DIOXIDE BY ANIMAL TISSUES

From the point of view of general physiology, Evans's summary¹ of the rapidly increasing evidence that carbon dioxide can be utilized by higher animal tissues represents an important fundamental advance in current nutritional theory. Certainly it throws doubt on the validity of certain accepted clinical diagnostic methods.

For decades a sharp differentiation has been made between plant and animal nutrition, based on their basic nutritional requirements. Plants, with their ability to use simple inorganic substances such as carbon dioxide, ammonia and water, have been placed in one category, sharply separated from animals, which apparently require more highly complex preformed dietary constituents. Experimentally it has been shown that the carbon requirements of higher plants can be satisfied completely by photosynthetic uptake of carbon dioxide. In animals carbon dioxide is traditionally regarded solely as a nonrecoverable metabolic end product.

The first serious break with this tradition dates from the demonstration by Wood and Werkman² of Iowa State College that certain saprophytic bacteria are able to utilize carbon dioxide as their sole source of carbon, under conditions that exclude the possibility of photosynthesis. Subsequently it was recognized³ that in algae and in higher plants there are two methods of carbon dioxide utilization, a photosynthetic uptake ("light assimilation") and a nonphotogenic fixation, or carboxylation ("dark assimilation"). A hint that a similar nonphotogenic incorporation of carbon dioxide into organic molecules also occurs in animals came as a by-product to studies of carbohydrate metabolism. By the use of radioactive carbon dioxide, or the stable isotope of carbon, Wood and his co-workers,⁴ for example, showed that the tagged carbon dioxide ($C^{13}O_2$)

is incorporated anaerobically into malic, fumaric and succinic acid in minced pigeon muscle. Evans and Slotin⁵ showed its similar incorporation into alpha-ketoglutaric acid and its presumptive incorporation into lactic acid. Under certain experimental conditions the uptake of ($C^{13}O_2$) by minced rat, pigeon or beef liver may equal 25 to 30 per cent of the total earmarked carbon dioxide originally added to the suspension fluid.

Afterward Solomon and his associates⁶ of Harvard Medical School showed that a similar utilization of carbon dioxide takes place in intact animals. These investigators injected radioactive sodium bicarbonate into fasting rats and simultaneously fed the animals with sodium lactate. They found that a considerable part of the injected radioactive carbon appeared as new formed glycogen in the liver. Less than 60 per cent of the injected C^{11} was accounted for in the respiration and other excretions, suggesting that over 40 per cent of the carbon dioxide was retained in organic combination in various tissues.

In order to determine the chemical nature of this tissue utilization of carbon dioxide, Evans and his associates⁷ have begun a study of $C^{13}O_2$ uptake by cell free tissue extracts. In fresh aqueous extracts of minced pigeon liver there is an initial rapid utilization of $C^{13}O_2$, followed by its gradual release. This suggests that there are two different (or reversible) enzymic reactions involved, one bringing about a rapid assimilation of carbon dioxide, the other its slow release. In cell free phosphite buffer extracts of pulverized acetone dried pigeon liver, in contrast, there is a steady and constant increase in the carbon dioxide uptake, over 20 per cent of the inorganic C^{13} being fixed as organic carbon by the end of sixty minutes' anaerobic incubation at 40 C. This suggests that the enzyme responsible for the terminal release of carbon dioxide is either absent or inhibited in this extract.

Thus far too little quantitative work has been done with intact animals to predict the magnitude of the error that nonrecognition of metabolic reutilization of carbon dioxide introduces in current clinical methods. If it can be shown that 10 per cent of the carbon dioxide nutritional end product is reutilized under certain conditions while the suggested 40 per cent is conserved under other conditions, a very appreciable error will be recognized. The work is of main interest at the present time, however, as exemplifying the radical revisions of traditional theories that may result from current studies of the physiology of "tagged" atoms and other "earmarked" chemical products. There is a wide range of clinical beliefs that conceivably will soon become obsolete.

PROTEIN DEFICIENCY

For several decades it has been known that animals placed on a diet deficient in protein develop a hypoproteinemia. Weech and his associates¹ of Columbia University, for example, showed that the decrease in serum protein is almost exclusively in the albumin fraction, the serum globulin remaining practically constant. It had been previously suggested by Holman and others² that there is a "dynamic equilibrium between tissue protein and plasma protein," though no serious attempts were made to determine the mathematical laws governing the presumptive intracellular-extracellular protein interchange.

During the course of extensive nutritional experiments Sachar and others³ at Washington University, St. Louis, obtained evidence in support of this assumed constant physicochemical balance. In a series of dogs maintained for three weeks on a protein free diet, for example, there was a fall in total serum albumin, calculated from the fall in albumin concentration multiplied by the total blood volume. The accompanying loss of fixed tissue protein was calculated from the total urinary and fecal loss of nitrogen, 1 unit of nitrogen being equivalent to 6.25 units of protein. In their first group of protein starved dogs there was a constant ratio between the total serum albumin loss and the fixed tissue protein depletion. For example, the average loss of total serum albumin was 5.28 Gm, with an average total body depletion of 176 Gm. This is a 30:1 ratio between tissue depletion and serum loss. The available data in the clinical literature suggest that the same mathematical relationship holds for man.

The practical therapy of dietary protein deficiency has been studied by numerous investigators. Weech,⁴ for example, found a definite regeneration (in the fol-

lowing order of efficacy) when beef serum, egg white, meat, liver or casein was added to canine deficiency diet. After three weeks' protein starvation a supplementary diet of 5 Gm per kilogram daily of beef chuck led to an almost complete return to normal within ten days. This is equivalent to approximately 1 pound of beefsteak daily for the average human adult. In order to determine the maximum rapidity of such regeneration,

the St. Louis surgeons⁵ allowed a group of dogs starved of protein for three weeks to eat raw lean horse meat ad libitum over a two weeks period. The amount of meat voluntarily consumed by these dogs was surprisingly large, averaging 250 Gm per kilogram daily, each dog consuming each day approximately one fourth of its total body weight. This would be equivalent to 12½ pounds of beefsteak three times a day for the average human adult.

This massive protein diet resulted in a complete regeneration of both concentration and total amount of serum albumin within one week. The total circulating serum albumin increased well above normal, mainly as a reflection of the increased plasma volume. The changes in body weight were roughly parallel with the changes in total serum albumin. There was little further increase in total serum albumin during the second week. The serum globulin, which remained unchanged during the first week, however, showed a distinct increase during the second week. The red cell volume fell during the regeneration period, presumably as a reflection of the increased total blood volume.

The St. Louis surgeons conclude that the 30:1 partitive coefficient between total tissue protein and serum albumin makes the use of human plasma or serum transfusion altogether impractical in clinical cases, at least in severely depleted patients. They are of the opinion that the most promising therapeutic approach at the present time is by the use of hydrolyzed proteins of "high biologic value."⁶

MORE YOUNG PHYSICIANS FOR THE ARMY

Under Medicine and the War in this issue of The Journal appears a statement authorized by the Office of the Surgeon General relative to the recruitment of physicians for the Medical Department of the Army. The points made in that statement may be succinctly stated as follows:

1 Doctors who volunteered in 1940 and early in 1941 must be promoted, so that doctors who volunteer now should not expect initial appointments in the higher grades.

2 Active recruitment must continue to keep pace with the needs of the armed forces. Doctors declared available by the Procurement and Assignment Service are now being directly recruited by the Medical Corps.

3 Young physicians are most needed. In many places they seem to be reluctant to enroll. The Surgeon General requests older physicians to urge enrolment of these younger men.

4 The official way to volunteer is application on the regular War Department forms. No other method of volunteering is official.

5 Every effort is being made to assign men with special training to the work for which they are best fitted.

6 Read particularly the five paragraphs under the heading "Some Don'ts." Cooperation will aid efficiency necessary to win the war.

Current Comment

FUEL OIL RATIONING

Under correspondence in this issue of THE JOURNAL, page 472, appears a letter from Joel Dean, director of the Fuel Rationing Division of the Office of Price Administration relative to aspects of this subject which especially concern the physician. Illness, old age or infancy may make necessary auxiliary rationing of oil, consumers may obtain such auxiliary rations by applying to the local rationing board, accompanying the application with a certificate from a licensed physician. In supplying such a certificate the physician is to give the date, the name and the address of the householder. Furthermore, he must certify the nature of the illness, whether acute or chronic, whether or not it is of the type requiring higher indoor temperature, the approximate temperature required and the approximate period for which the supplemental base heat is needed. The physician may at his discretion state the nature of the illness or may give additional information that will be helpful. The applicant himself files the certificate with the local rationing board. Furthermore, as a check, advisory committees are to be set up for each local rationing board. These advisory committees will include two licensed physicians and the county or local health officer. They will review cases in which certificates are questioned or in which a professional opinion is desired. Thus comes to the medical profession another call for its special services in wartime. Civilian physicians will no doubt do their utmost to aid in this work as another contribution to the war effort.

PNEUMONIA DEATH RATE DECLINING

The decline in the pneumonia death rate from 202.2 per hundred thousand in 1900 to 70.3 in 1940, reported by the federal Bureau of Census, is by no means as glowing as the results in the last two years entitle us to expect. This statement by Dr. Louis I. Dublin of the Metropolitan Life Insurance Company lends emphasis to the realization that the use of sulfonamide derivatives and other modern treatments have greatly accelerated the decline of the influenza and pneumonia death rate in the past two years and that we may expect even greater diminution. For the first seven months of 1942 the death rate of the Metropolitan Insurance Company's industrial policyholders from influenza and pneumonia was 28 per cent below the corresponding period of 1940. Dr. Dublin says:

How remarkable this drop in mortality really is can only be realized by thinking in terms of the decline per year over the four decades from 1900 to 1940, and the corresponding annual figures for the last two years.

For the general population, the decline in influenza and pneumonia mortality has been at a rate of 15 per cent a year in the four decades. Among the insured wage earners and their families the rate of decline in the last two years has been more than 14 per cent a year. And much the same results will probably be found to have occurred in the general population when the mortality figures become available. Indeed, if the present trend continues for a few more years, pneumonia, which only a decade ago was a scourge, will have become a minor cause of death.

THE HUMORAL CONTROL OF INTERNAL SECRETION

Probably the most direct evidence for the humoral control of endocrine secretion so far reported is that presented by Patt and his co-workers¹. Three types of experiments for testing the response of the parathyroid glands to low serum calcium were undertaken. First, small dogs were alternately bled maximally and immediately transfused with an equal volume of decalcified blood. By this means the total serum calcium was decreased to 5.5 to 7 mg per hundred cubic centimeters after about fourteen transfusions. Twenty minutes after the last transfusion the serum calcium rose 1 to 2 mg in both the normal dogs and in dogs thyroparathyroidectomized just prior to the experiment, and no further rise in serum calcium was observed. These experiments were performed on 7 normal and 3 thyroparathyroidectomized dogs. Second, large amounts of sodium oxalate were injected intravenously into both normal dogs and dogs thyroparathyroidectomized just prior to the oxalate injections. In both groups of animals the serum calcium fell immediately to 5.5 to 7 mg per hundred cubic centimeters but rose promptly in the intact dogs and returned to the normal level within one and one-half to three and one-half hours. Only a slight rise in serum calcium (1 to 2 mg per hundred cubic centimeters) occurred in dogs deprived of their parathyroid glands, nor was any rise noted during a subsequent seven hour period. In this series 5 normal and 4 parathyroparathyroidectomized animals were used. The most direct evidence was secured in a third series of experiments in which the thyroid-parathyroid gland in a dog was isolated from the systemic circulation, only the superior thyroid artery and the internal jugular vein being left open. These vessels were cannulated. Decalcified heparinized blood was perfused through the gland for two hours at a rate of approximately 3 to 4 cc per minute. The plasma of this perfusate was then injected intravenously into a normal dog under soluble barbital anesthesia. A rise in serum calcium of from 1.6 to 4.5 mg occurred one and one-half to three hours later. The calcium returned to normal in four and one-half to seven hours in 4 of the dogs but remained elevated in 3 dogs seven hours after the injection. When normal heparinized blood was perfused through the thyroid-parathyroid apparatus, the collected perfusate on intravenous injection did not yield any significant change in serum calcium. In this last series of experiments serum phosphorus values were also determined, but the changes observed were not considered significant since urinary phosphorus values were not followed simultaneously. Eleven such experiments involving the perfusion of both decalcified and normal blood were carried out. These preliminary investigations are considered by the authors to indicate a humoral control (low blood calcium) of the parathyroid glands. Such humoral control of endocrine secretion is suggestive of the homeostatic mechanism for the regulation of the blood sugar by the liver, as reported by Soskin and his co-workers² in 1938 and marks an important step in the understanding of the mechanism by which physiologic change is controlled.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

THE NEED OF THE ARMY FOR PHYSICIANS

The office of the Surgeon General, United States Army, Washington, D. C. has requested publication in THE JOURNAL of the following statement

RANK ON INITIAL APPOINTMENT

The Surgeon General realizes that physicians of our country are being asked to make individual and collective sacrifices incomparably greater than those of other professional groups. Original appointments in higher grades no matter how desirable, cannot be recommended for all physicians in order to compensate them for their sacrifices which must be faced both on a financial and on a familial basis. The physician must accept these sacrifices with his heritage of altruistic devotion to suffering humanity which is universally anticipated. In justice, however, to those medical officers who accepted in peacetime their obligation of service to our country, and who during the long months since August 1940 have made possible an adequate medical service for our ever increasing army, initial appointments of new officers in grades to which qualified officers already in service should be promoted must necessarily be restricted.

RECRUITMENT MUST CONTINUE

The response of the medical profession to the Army's request for medical officers has been most gratifying. However, active recruitment throughout 1943 will be necessary to keep pace with the accelerated mobilization rate.

The Procurement and Assignment Service of the War Manpower Commission has furnished a tremendous aid in the procurement of applicants and in furnishing necessary information regarding their professional qualifications and availability for military service. Recently this service has furnished the Surgeon General with names of qualified, eligible physicians who have signified their desire to enter the Medical Department and are not considered essential to the health and safety of the civilian community. These physicians are being requested, either directly or through the medical officer recruiting boards in various states, to make application for appointment in the Medical Corps.

YOUNG MEN MOST NEEDED

In regard to this, it must be borne in mind that acceptance by the armed forces of applicants above Selective Service age tends to create in civil communities a shortage of doctors. This may result in deferment of younger men whose prerogative it is to serve. Young physicians must be procured for assignment to duty with combat troops, both of the army ground forces and of the army air forces. Of vital interest is

the fact that a relatively small percentage of recent graduates in medicine who completed one year of internship have accepted the responsibilities of military service. This group of physicians, and those slightly older, are the ones on whose shoulders the responsibilities for adequate military care must fall. The Surgeon General urges the physicians who served in the first world war, who so loyally offer their services in the present emergency, to utilize their prestige and influence to persuade the younger men to accept their responsibility in the national war effort, as the physicians of 1917 and 1918 accepted theirs.

HOW TO VOLUNTEER

From correspondence received in the Office of the Surgeon General, it is apparent that many unanswered questions should be explained. To help clear this maze of doubt, a few questions will be answered and clarified in the following paragraphs.

First, have you volunteered? Only if the following conditions have been fulfilled:

- 1 If you have filled out application blanks at a medical officers recruiting board and have had a final type physical examination at an army installation.

- 2 If you have filled out these blanks and sent them to the Office of the Surgeon General, with the report of your physical examination.

- 3 If you are already in the service.

A personal letter written to the Surgeon General applying for duty is not sufficient, neither is the completion and return of questionnaires such as those distributed by the Procurement and Assignment Service of the War Manpower Commission sufficient. You must apply on regular War Department forms to the Surgeon General directly or through the medical officers recruiting board before you have volunteered your services. The latter is preferable (application through the medical officers recruiting board), for it allows completion of the essential papers more rapidly than can otherwise be accomplished. So, contact your board. Physicians who are designated by the Procurement and Assignment Service as "essential" for civilian medical services cannot be commissioned and should not initiate applications for commissions.

ASSIGNMENT TO SPECIAL SERVICES

What kind of work will you do?

A sincere effort is being made by this office to place men in the same type of work for which they received training in their civilian medical practice. The papers of every officer appointed are examined carefully before assignments are made. Those individuals who have had special training in any field of medicine can best serve

their country doing that work. We are hoping not to have ophthalmologists doing amputations of extremities. We do not wish to have general surgeons as chiefs of radiology departments. It will be impossible to classify every individual properly, but at the present time the vast majority of men are being placed as their training indicates, by automatic processes in the Surgeon General's office. Therefore you, if a specialist, can be assured that every effort will be made to continue you in an assignment in keeping with your training and experience. This will keep the level of military medicine on a high plane and at the same time further the education of the individual concerned and increase the standards of medical care for the soldiers in the front lines.

SOME DON'TS

To help the Surgeon General, please observe the following:

1 Do not come to Washington to talk to officers engaged in this work. Your presence slows the call to active duty of many men.

2 Do not try to influence this office by the writing of letters to influential individuals in other government services. Their time is already engaged in functions essential to successful completion of our war effort.

3 Do not send in duplicate applications. This results in much confusion in all War Department offices concerned in the calling to duty of qualified physicians.

4 Do not write for information unless it is absolutely essential and of an emergency nature. Many letters are answered daily which, on proper consideration, should never have been written, or the answers could have been given by medical officers recruiting boards.

5 The action of the grading committee appointed in this office in determining the initial grade must be final. The decision is reached only after careful consideration of many factors which must be taken into account and cannot possibly be understood by one not in the military service.

NOW IS THE TIME TO VOLUNTEER!

Our army is a young army. It needs young doctors—doctors of troop age, 45 years or younger—men who can work in the field hospitals, mobile hospitals and other medical installations. Doctors above this age should take care of civilian medical needs, a necessary patriotic service, unless a position vacancy awaits them in military service. The patriotic spirit of our country is, and must continue to be, reflected in the response of our doctors to this call to arms.

If you are in the age group needed, complete your application.

Your Army needs you!

Your Nation awaits your action!

PLANS TO MEET NEED FOR MEDICAL CARE

Plans for meeting the need for medical care in communities where a shortage of physicians has developed are being made now by the U. S. Public Health Service and the Procurement and Assignment Service of the War Manpower Commission. Paul V. McNutt, chairman of the War Manpower Commission, announced September 22. He added that the two services are cooperating closely in the planning of this emergency action.

Mr. McNutt explained that in many areas an acute need for medical service has arisen as a result of extraordinary increases in population brought about by expansion of war industries or other war activities. In other areas there is shortage of medical service resulting from the entry of physicians into the armed forces.

Distributed throughout the industrial areas of the country are more than three hundred communities in which the lack of medical care is being felt. The chairman pointed out that among the most critical of these localities are Baltimore County (around Glenn L. Martin Company), Valparaiso, Fla., Huntsville, Ala., Childersburg, Ala., LaPorte, Ind., Charleston, Ind., Fort Knox, Ky., Rantoul, Ill., Texarkana area, Bremerton, Wash., Pryor-Choteau, Okla., Vallejo, Calif., Velasco, Texas, Waynesville, Mo., Wichita Falls, Texas, and Norfolk, Va.

Mr. McNutt also announced his approval of a statement of policy adopted by the directing board of the Procurement and Assignment Service in which the Procurement and Assignment Service accepts the responsibility of ascertaining the needs of the civilian population for medical service and providing the medical personnel to meet them.

The principles set forth in this policy statement, Mr. McNutt said, were developed in cooperation with the federal officials concerned and have the approval of the Surgeon General of the United States Public Health Service. The statement has been approved by the boards of trustees of the American Medical Association, the American Dental Association and the war service committees of the two associations, and the executive committee representing the State and Territorial Health Officers Association.

Following are the principles recommended by the directing board of the Procurement and Assignment Service for meeting the emergency needs:

1 That it is a responsibility of the Procurement and Assignment Service to ascertain the needs of the civilian population—nonmilitary—for medical service.

2 That it is the responsibility of the Procurement and Assignment Service to aid in providing the medical personnel to meet these needs.

3 That, as now constituted, the Procurement and Assignment Service is not in a position to deal with the financial and administrative problems involved in the provision of medical care.

4 That as far as possible these problems should be met at the state level in view of the many different types of problems and needs and the relation of these and their solution to local situations.

5 That a survey of these needs should be made by the existing committees of the Procurement and Assignment Service with the aid of such technical assistance as may be necessary. It is especially desirable that in determining these needs the state procurement and assignment committee seek the cooperation of the state health department, of the state medical society and of the state dental society, of industry, of organized labor and of other agencies, such as the state defense council, which should be able to make significant contributions to the solution of this problem.

6 That whenever possible the civilian needs as determined by these committees should be met through local arrangements, resources and agencies. In case assistance is needed for the organization, administration or financing of necessary medical or dental services in these areas the responsibility should devolve on an agency which should include representatives of the state health department, the state medical society and the state dental society, with the cooperation and support—financial and technical—of the appropriate federal agencies, the administration of funds being delegated to the appropriate state agency.

7 That, since these problems have been occasioned by the war and in many instances transcend state lines, the federal government has a definite responsibility to cooperate with the states in meeting these needs by the provision, when necessary, of financial and technical assistance.

8 That the needs for medical care in certain areas are so acute and the pressure from various sources so great that it is imperative to have prompt action for implementation of this program. It appears to the directing board that the responsibility for the initiation of such action rests with the War Manpower Commission.

STATE MEDICAL CHAIRMEN FOR PROCUREMENT AND ASSIGNMENT SERVICE

Alabama—Dr B I Austin, 519 Dexter Avenue, Montgomery
 Arizona—Dr Charles S Smith Nogales
 Arkansas—Dr W R Brookshier 602 Garrison Avenue Fort Smith

WAR NEWS

HEALTH, SAFETY AND TECHNICAL SUPPLIES BRANCH

The Safety and Technical Equipment Branch has been consolidated with the Health Supplies Branch, the War Production Board announced, October 3. The new combined branch will be known as the Health, Safety and Technical Supplies Branch. Francis M Shields, formerly chief of the Health Supplies Branch, is chief of the combined branch. Mr Shields, before coming to the War Production Board, was vice president of the American Optical Company.

George W Angell, formerly deputy chief of the Safety and Technical Equipment Branch, has been named Deputy Chief under Mr Shields.

The Health, Safety and Technical Supplies Branch will embrace the following sections, each under the same section chief who headed it previously to its transfer to the newly created branch. Surgical Instruments Section headed by James H Burton, Orthopedic and Dental Section, Howard Pringle, X-Ray Section, R K Myers, Safety and Equipment Section, Harold C Mesch, Fire Equipment Section, H Mahlon Foley, Technical and Scientific Equipment Section, W C Stevenson.

GOVERNMENT PLACES RECORD ORDER FOR ATABRINE

Dr Theodore G Klumpp, president of Winthrop Chemical Company, disclosed on September 24 receipt from the U S Army of the largest single order for atabrine, synthetic substitute for quinine, on record. At the same time he revealed that production of atabrine in this country was now in excess of 500 million tablets a year and was rapidly approaching a rate of 600 million tablets a year.

It was announced also that the price of atabrine has been reduced to a new low of \$4.50 per thousand tablets. "The new price to the government," Dr Klumpp said, "reflects both recent increases in government orders and improvements in the manufacturing process. The \$4.50 price to the government compares with the former low of \$6 per thousand tablets and with \$66.66 in 1933, when atabrine was first introduced to the American medical profession. At the new low price it costs about as much to treat a case of malaria with atabrine as to send an airmail letter. Actually the cost of medication with atabrine is 6 3/4 cents per case, as compared with 27 cents for quinine."

VANDERBILT HOSPITAL UNIT ACTIVATED

The Vanderbilt University School of Medicine (Nashville) Unit, the 300th U S Army General Hospital, has been activated at Camp Forrest, Tenn. Lieut Col George W Reyer, M C, U S Army, is the commanding officer and Major James A Kirtley Jr is the unit director. Following are the other members of the staff.

SURGICAL SERVICE

Major James Addison Kirtley Jr	Capt Wilbur Kinsey Brubaker
Chief of Surgical Service	Capt Frank Wooldridge Buckner
Major Spencer Allen Collom Jr	Capt Henry Murfree Carney
Major Charles Fowler Hollibaugh	Capt Richard Redd Crutcher
Major James Andrew Mayer	Capt Dennis Bryan Fox
Major Francis Murphy	Capt Ben Hagan Marshall
Major John Lyle Shaw	Capt Edward Frost Parker
Major Charles Clay Trabue IV	Capt George Edgar Pryor
Major Harwell Wilson	Capt Louis Rosenfeld
Capt Ralph John Angelucci	

MEDICAL SERVICE

Major Perry Davis Priest Chief of Medical Service	Capt Malcolm Judd Mann
Major Arthur Bever Barrett	Capt John Christian Ransmeier
Major Clarence Lucas Garner	1st Lieut Robert Decker Beech
Major John Faulkner Ramey	1st Lieut Thomas Alison Donnell
Capt John William Allgood	1st Lieut Benjamin Perry Folk
Capt Robert Chambliss Berson	1st Lieut Laurence Abramam Grossman
Capt Robert Norman Buchanan	1st Lieut Herman Levinson
Capt Joseph Russell Cook	1st Lieut Hugh Harrison Mills
Capt Robert Mark Finks	1st Lieut Richard Winston Blum berg
Capt Wiley Lewis Forman	
Capt Joseph Wilson Johnson Jr	

DENTAL SERVICE

Capt Thomas Joseph Dowling	Capt James Benton Neil
Chief of Dental Service	1st Lieut Sifford Carmack Garvin
Capt George Wheeler Matthews	

LABORATORY SERVICE

Capt David King Gotwald Chief of Laboratory Service	1st Lieut Beverly Todd Towers
---	-------------------------------

X-RAY SERVICE

Capt John McDougall Chief of X Ray Service	1st Lieut Ben Richardson Mayes
--	--------------------------------

MEDICAL ADMINISTRATIVE

Major John Sims Crutcher Jr	1st Lieut Garth Fort
Major Robert Knox Galloway	1st Lieut Thomas Shadrack Weaver
1st Lieut Holger Kermit Brask	

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—Public hearings are being held by a subcommittee of the House Committee on Education on H R 7484, a bill providing for the vocational rehabilitation of individuals suffering from war connected or other disabilities. The conference report on H R 7164, to amend the Soldiers' and Sailors' Civil Relief Act of 1940, has been agreed to by the House and Senate. The bill retains the provision authorizing the cancellation of leases on premises occupied for professional and certain other purposes. S 2676 has been reported to the House, providing for medical care and funeral expenses for members of the Naval Reserve Officers' Training Corps who suffer disability from personal injury, illness or disease occurring in line of duty.

Bills Introduced—S 2814, introduced by Senator Walsh, Massachusetts, for himself and Senator Clark of Missouri, and

H R 7618, introduced by Representative Rankin, Mississippi, provide for the rehabilitation in civil employment of persons disabled in the active military or naval service in the present war. H R 7614, introduced by Representative Eberharter and H R 7622, introduced by Representative Weiss both of Pennsylvania, propose to increase the annual base pay of female nurses of the Army and Navy to \$1,800.

DISTRICT OF COLUMBIA

Change in Status—S 2804 has been reported to the Senate, a bill to define the real property exempt from taxation in the District of Columbia. Among other things this bill exempts from taxation hospital buildings belonging to and operated by organizations which are not organized or operated for private gain including buildings and structures reasonably necessary and usual to the operation of a hospital.

MEDICAL ECONOMIC ABSTRACTS

MEDICAL PLANNING IN GREAT BRITAIN

The Medical Planning Commission, established by the British Medical Association with the cooperation of the Royal Colleges and the Royal Scottish Corporations in August 1940, has submitted a draft interim report to the recent meeting of the British Medical Association.¹

After discussing the defects of the present medical services, the commission sets forth some of the principles by which the discussions have been guided.

What steps should be taken in the public interest to improve the community's medical services as a whole? Any proposals for reform must have as their object the largest possible measure of improvement in the public health. They must aim at improvement in the quantity, the quality and the availability of all types of medical service. Doctors must be competent and have time to devote to those medical services which they undertake to give. They must have facilities for rendering them at the highest possible level of efficiency. The public must have access to all services with the maximum amount of convenience and comfort.

The reform of the medical and health services of the country should include measures for securing that each family or individual shall be under the care of a medical practitioner who shall be concerned not only with diagnosis and treatment but also with the promotion of health and the prevention of disease. This involves the integration of the preventive and personal health services. It also involves radical changes in the country's administrative machinery and in the training of medical students. It assumes that the fusion of public health and other forms of practice will result in practitioners in every field working in closer contact and accord not only with one another but also with dentists, nurses, midwives, sanitary inspectors and other auxiliaries.

The organization of all hospital services on a regional basis is generally favored, but there is division of opinion as to the action to be taken with regard to medical services. Some would favor an evolutionary development of existing services, with an expansion and improvement of the system of health insurance, supplemented by the creation of health centers to provide better facilities for consultation and diagnosis.

Another group desires a whole time salaried medical service organized locally through a system of health centers so placed and staffed as to meet the needs of the population, linked with the hospitals and all specialist services. Opponents of this plan "fear the intrusion of politics, both national and local, into the field of medical service, an intrusion which they maintain would be disastrous. They hold, further, that the 'cold hand of bureaucratic control' with the doctor acting under the orders of superior officers whether medical or lay would be inimical to the wise and humane administration of a personal health

service. The free lance doctor turned civil servant, they say, would suffer a diminution of his sense of personal responsibility for his patient and he would lose the spur to improved professional work and research. A profession of routine 'safe men' would be to the detriment of the country's health, and medicine might cease to attract the proportion of first class men it has attracted hitherto."

An intermediate group "are yet not prepared to go so far as to recommend a whole time salaried medical service. They therefore suggest a service intermediate between the two which would be based primarily on part time salaried public service with opportunities for private practice. The following outline may be taken as a typical intermediate scheme. Domiciliary medical service for persons with incomes below a certain level with their dependents, would be free, persons whose income is above the standard 'free' level but below another standard figure would have the option of 'contracting in' to the service by making payments at regular intervals to a contributory scheme. The young practitioner entering general practice would act as assistant and receive a salary. The salary of the principal would depend upon the number of 'public' patients allocated to him, and this in turn would be dependent inversely upon the number of his private patients. The scheme also provides for the appointment of district medical officers with supervisory and consultative functions. An ad hoc regional council composed of full time salaried representatives of local authority hospitals and the local profession would be responsible directly to the central authority for the proper functioning of the domiciliary medical service in its area. The cost of the service would be a direct charge on the exchequer."

The majority is against a whole time salaried government service and feels that it is impossible to "start with a clean slate." The plan which is submitted for discussion would give the medical profession a greater influence in the local administrative bodies than exists in the present organization of medical services. It would encourage the development of group medical centers but would not make such institutions compulsory. Greater opportunity would be given to practitioners in the hospitals to acquire both clinical and administrative skill. Specialist and consultant services would be made more readily available. As few restrictions as possible would be placed on free choice. Special attention and provisions should be made for industrial service. The report concludes with list of points on which it asks for general discussion by the profession.

Medical News

(PHYSICIANS WILL CONFERR A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ARKANSAS

Personal—Dr. Louis L. A. Baldridge, Conway, has been appointed health director of Franklin County.—Dr. Arthur C. Curtis, State Sanatorium, has been appointed director of the division of tuberculosis control of the Arkansas State Board of Health.—Dr. John R. Kitley has been reelected mayor of Mayflower for the seventeenth term.

District Meeting—The Tenth Councilor District Medical Society was addressed in Fort Smith, September 24, by Major Warner F. Bowers on "Traumatic Chest Surgery", Major Farris D. Evans "Traumatic Abdominal Surgery", Capt. David I. Schwartz, "Management of Compound Fractures," and Lieut. Norman F. Richard "Nature and Treatment of Shock". All are of Camp Claiborne. The district society is composed of Benton, Washington, Crawford, Sebastian, Scott, Madison, Franklin, Johnson and Logan counties.

CALIFORNIA

Criminal Action Filed Against Impostor Phillips—J. W. Williams, San Francisco, representing the state board of medical examiners, has filed a criminal action in the court of Justice Gildersleeve at Fort Bragg against "J. H. Phillips," charging Phillips with unlawful practice and attempt to practice a system and mode of treatment in violation of the business and professional code of the state of California, newspapers reported on September 3. Arthur Osborne Phillips, alias "Dr. James Herman Phillips," is now said to be serving a term in the Butte County jail at Chico having been found guilty of a charge of possessing a concealed weapon. His sentence on this charge is running concurrently with a six month sentence imposed after conviction on charges of practicing medicine without a license, it was reported. The new complaint will not be pressed until Phillips is at liberty. On May 26 he was charged with impersonating a surgeon and performing operations without a license in the Enloe Hospital in Chico where he served temporarily as chief resident and chief assistant surgeon. Despite his claims prior to conviction, Phillips never graduated from a medical school. His diploma was obtained under a false affidavit and his confession admitted that he was an ex-convict. A complete record of Phillips's activities which was published in THE JOURNAL September 12, page 145, indicates that he served sentences for practicing medicine without a license in Alabama and Idaho. He served sentences on other charges in Ohio, Georgia, Pennsylvania and Maryland.

COLORADO

Personal—Dr. Robert K. Dixon, Denver, has been appointed a member of the state board of medical examiners to succeed Dr. George R. Buck, who entered the U. S. Navy Medical Corps. Dr. John B. Davis, Denver, is the secretary-treasurer of the board.

Society News—The Arapahoe County Medical Society was addressed recently in Englewood by Robert A. Downs, D.D.S., director of the subdivision of dental health of the state division of public health, Denver, on "Control of Dental Caries."—A symposium on alcohol was presented before the Medical Society of the City and County of Denver by Drs. Philip Work, John P. Hilton and Bradford J. Murphey, August 4, all of Denver. Dr. Ora L. Huddleston, Denver, discussed "Physical Therapy in the Practice of Medicine" before the society, September 1.

CONNECTICUT

Society News—Dr. Paul D. Rosahn, New Britain, was reelected president of the Connecticut Society of Pathologists at its annual meeting in New Haven, and Dr. Robert Tennant, Hartford, was chosen secretary-treasurer.—Dr. Readie Griffield Snyder, New York, discussed "Recent Advances in the Treatment of Arthritis" before the Bridgeport Medical Society in June. Dr. Edward Lodholz, Philadelphia, addressed the May meeting on "The Biology of Senescence."

Original Treatises Presented to Yale—Print Collection Established—Dr. Joseph Marshall Flint, professor of surgery at Yale University School of Medicine, New Haven, from 1907 to 1921 and for the past twenty-one years in retire-

ment in Vevey, Switzerland, has presented to Yale a group of medical texts including original treatises by Vesalius, Fabricius and Tagliacozzi. The John E. Lane Collection of prints has been established at Yale to be built up around a nucleus of one hundred and thirty-six medical engravings given to the library by Dr. George Blumer, David P. Smith, clinical professor of medicine, emeritus. The John E. Lane Collection will include, in addition to Dr. Blumer's gift, the entire collection of prints belonging to the medical school, many of which came to the library through Dr. Harvey Cushing's bequest, as well as all other prints which may be added in the future. The collection is named in memory of the late Dr. John E. Lane, a former member of the faculty, who received his M.A. degree from Yale in 1897 and his M.D. in 1903. He was chairman of the Section on Dermatology and Syphilology of the American Medical Association in 1924-1925.

GEORGIA

Twenty-Five Years Director of Health Department—Dr. Thomas F. Abercrombie, Atlanta, completed twenty-five years as director of the Georgia Department of Public Health on August 1. He was born in Doughertyville and graduated in 1903 at the Atlanta College of Physicians and Surgeons, now a part of Emory University. He was a member of the Rockefeller Sanitation Commission from 1911 to 1913 and commissioner of health of Brunswick and Glynn County from 1914 to 1917, when he became state health director.

ILLINOIS

Professor of Chemistry Goes to Winthrop Company—Chester M. Suter, Ph.D., professor of organic chemistry, Northwestern University, Evanston, has been appointed director of chemical research of Winthrop Chemical Company, Inc., at Rensselaer, N. Y. Dr. Suter received his Ph.D. at the University of Kansas in 1927.

Chicago

Dr. Kendall Retires—Arthur I. Kendall, Ph.D., Dr. P.H., research professor of bacteriology at Northwestern University Medical School, retired, effective September 1. Dr. Kendall is 65 years of age. A native of Somerville, Mass., he received the Ph.D. at Johns Hopkins University, Baltimore, in 1904 and the Dr. P.H. at Harvard University, Boston, in 1911. Early in his career Dr. Kendall was acting chief of the board of health laboratory of the Isthmian Canal Commission, Panama, fellow of the Rockefeller Institute and instructor in the department of preventive medicine and hygiene at Harvard Medical School. He was professor of bacteriology and director of the Patten Research Foundation at Northwestern from 1912 to 1924 and dean of the medical school from 1916 to 1924. He went to Washington University School of Medicine, St. Louis, 1924 as professor of bacteriology and public health but returned to Northwestern in 1928 as research professor of bacteriology. In 1918 he was chairman of the yellow fever commission of the International Health Board of the Rockefeller Foundation.

Presbyterian Hospital Reorganized—A general plan of reorganization has taken place at Presbyterian Hospital involving many changes of administration. Dr. Carl W. Apfelbach, in the newly created position of medical director, has been placed in charge of the administration of the hospital, the school of nursing, the Central Free Dispensary and the physical plant of Rush Medical College. Mr. Herman Hensel, who has been assistant superintendent for fifteen years of his twenty-nine years' affiliation with Presbyterian, is now superintendent of the hospital, succeeding Mr. J. Dewey Lutes, resigned. He will supervise the work of the maintenance, housekeeping, laundry, dietetics and clerical departments of the hospital. Mr. Asa Bacon, superintendent emeritus, is assisting the new administration as consultant. The Central Free Dispensary, which for a number of months has been under the supervision of the hospital, is now operating as the outpatient department of the hospital. The buildings of Rush Medical College have been leased to the hospital, which is responsible for the medical education program and research carried on in it. The students of University of Illinois College of Medicine benefit from these facilities under the school's new affiliation with Presbyterian Hospital. Under the new setup Rush retains the privilege of using 15 per cent of the space in the Senn, Rawson and laboratory buildings in a continuance of its program of graduate education. It functions independently under the direction of a board of trustees which controls the funds for its maintenance. Its faculty consists of the following physicians: Vernon C. David, surgery; Ralph C. Brown, medicine; Noble Sproat Heaney, gynecology and obstetrics; Clifford G. Grulee, pediatrics; James Herbert Mitchell, dermatology; Daniel B. Hayden, otolaryngology; Peter Bassoe, neurology; Edward V. L.

Brown ophthalmology, and Dr Apfelbach, pathology, all of whom are on the staff of the University of Illinois. All members of the staff of Presbyterian Hospital are also members of the faculty of Illinois. Mr Charles B Goodspeed was recently elected president of the board of managers of the hospital and Dr Heaney president of the hospital staff.

INDIANA

Changes in Health Officers—Dr Daniel D Jones of Beane has been appointed health officer of Adams County.—Dr Arthur Leiter, Columbia City, has been appointed health officer of Whitley County.—Dr Laurence E Jewett has been appointed health officer of Wabash, succeeding Dr Robert M LaSalle, who resigned to enter army service.

Personal—Dr Francis V Martin, Michigan City, was guest of honor at a dinner given by the La Porte County Medical Society on July 5 in honor of his completion of fifty years in the practice of medicine.—Dr Mattie J Bullard, Gary, has been appointed city school physician to succeed Dr Charles P Anderson, Gary, who has entered army service.—Dr John W Webb, Indianapolis, and Paul R Tindall, Shelbyville, have been appointed members of the Indiana State Board of Medical Registration and Examination to succeed Drs Hugh W Eikenberry, Peru, and Galt T Bowers, Fort Wayne, respectively.

KANSAS

City and County Health Units Combine—The health departments of Topeka and Shawnee County have been combined to promote efficiency and economy. Dr David D Carr, health officer of Topeka, has been placed in charge of the new unit and a supervising board includes Drs Floyd C Tiggart, chairman, Paul E Belknap, Milton B Miller, William C Menninger and Clyde S Smith, Rossville.

MASSACHUSETTS

Society News—Dr Donald J Slaughter, Burlington, Vt., will address the New England Society of Anesthesiology in Boston November 10, on "New Concepts of Morphine Analgesia." Major Stevens J Martin, Fort Dix, N. J., will discuss "Role of an Anesthesiologist in the Army" before the society on October 13.

Lectures on Alcoholism—The following series of lectures on various aspects of alcoholism will be given at the Washington Hospital, Boston: Drs Maurice B Strauss, October 25, "Alcoholism and Its Effect on the Organs of the Body," Abraham Myerson, November 15, "Alcoholism and Its Effect on the Mind," and Joseph Thimann, January 17, "Modern Medical Treatment of Acute and Chronic Alcoholism." All speakers are of Boston. These lectures will be open to the public but admission to the round table discussion on alcoholism February 14, will be by invitation only.

MICHIGAN

Changes in Health Officers—Dr George F Moench, acting head of the Calhoun County Health Department at Marshall, has been appointed director of the Hillsdale County Health Department to succeed Dr Jacques P Gray, who resigned to become dean of the Medical College of Virginia, Richmond.—Dr James A Olson, Flint, director of the Mott Foundation Children's Center and director of health for the Flint Public Schools, has been appointed acting executive health officer of Flint until a successor to Dr George Hays can be selected by civil service for the duration of Dr Hays's leave of absence.—Dr Raymond G Tuck, Royal Oak district health officer in Southern Oakland County, has been appointed health officer of Hazel Park, he will continue to serve as district health director.

Personal—Dr J Earle McIntyre, Lansing, secretary of the Michigan State Board of Registration in Medicine has been elected a member of the National Board of Medical Examiners.—Dr LeMoyne Snyder, Lansing, has been appointed deputy chief of the emergency medical service in the Michigan Council of Defense to fill the vacancy left by Dr Lloyd H Gaston, Lansing, who has been commissioned as a surgeon in the reserve corps of the U. S. Public Health Service.—Drs David H O'Donnell and Edward J Panzner, both of Detroit, were recently presented with the Distinguished Citizen's Medal by the Veterans of Foreign Wars of the United States for their contributions to the Veterans of Foreign Wars.—Dr Lowell T Coggeshall, professor of epidemiology, University of Michigan School of Public Health, Ann Arbor, has returned from a three months trip in Africa and the various Middle East countries while serving as director of the air corps ferrying command medical officers, Pan American African Airways.

Dr Coggeshall is now directing the Pan American African medical staff from his office in Ann Arbor. Dr George M Jones Jr, instructor in internal medicine at the University of Michigan Medical School, is a member of the African staff, other members were chosen from medical schools all over the United States, it is reported.

Extramural Course for Physicians—The semiannual postgraduate course for graduates in medicine, given under the auspices of the state medical society in cooperation with the University of Michigan Medical School, Ann Arbor, Wayne University College of Medicine, Detroit, and the state department of health opened on October 1 in Lansing. Sessions have already been held in Battle Creek and Ann Arbor but a second series of lectures will be presented in both places on October 20 and November 12, respectively. Other centers and dates for the lectures have been announced as follows: Flint, October 13 and 27; Grand Rapids, October 13, November 1, Mount Clemens, October 14 and 28; Saginaw, October 13, November 10 and Traverse City, October 14 and November 11. Topics include surgery of the ambulatory patient, modern treatment of cardiac failure, acute conditions of the abdomen, psychosomatic medicine, the industrial dermatoses and fungous disease of the skin and accidents and complications of the newborn period and postpartum care. Local hospitals and county medical societies are cooperating in the project, which is offered without charge to practicing physicians. A course is planned for Houghton, Ironwood, Marquette, Powers and Sault Ste. Marie during the week of May 24-28, the subjects to cover the problems in internal medicine, general surgery, pediatrics and obstetrics and gynecology.

MINNESOTA

The Jackson Lecture—Dr Thomas Francis Jr, professor of epidemiology, University of Michigan School of Public Health, Ann Arbor, Mich., will present the annual Clarence Martin Jackson lecture in the Medical Science Amphitheater, University of Minnesota, Minneapolis on "Interpretation of Current Studies in the Control of Epidemic Influenza." The lecture is sponsored by the chapter of Phi Beta Psi.

Professor Ross Gortner Dies—Ross A Gortner, Ph.D., professor of agricultural biochemistry and chief of the division of agricultural biochemistry, College of Agriculture of the University of Minnesota and Minnesota Agricultural Experimental Station St. Paul, died on September 30 of heart disease aged 57. Dr Gortner was a member of many scientific societies and during his career had received many awards, his work accounted for numerous contributions in the field of biochemistry. This year the American Association of Cereal Chemists awarded him its Osborne Medal for his accomplishments in the chemistry of cereals and the improvement of bread flours.

Southern Minnesota Meeting—The Southern Minnesota Medical Association was addressed at its annual session in Rochester, September 28, among others, by

Dr Paul R Lipscomb, Rochester, Fractures of the Astragalus
Dr Paul A O'Leary, Rochester, Technique for Intravenous and Intramuscular Administration of Antisplenic Remedies
Dr Edward C Rosenow, Rochester, Poliomyelitis, Antistreptococcal Serum in the Diagnosis and Treatment of Epidemic and Experimental Poliomyelitis.

One feature of the session was a symposium on civilian and industrial accidents.

Dr Howard K Gray, Rochester, Chest Injuries
Dr Roscoe C Webb, Minneapolis, Injuries to the Abdomen
Dr Ralph K Ghormley, Rochester, Compound Fractures
Dr Henry H Young, Rochester, Gas Gangrene of the Extremities
Dr Paul F Dwan, Minneapolis, Preparation of Human Serum
Dr William H Bickel, Rochester, Treatment of Shock and the Plasma Treatment of Burns
Dr Elmer C Wakefield, Rochester, Heat Strokes.

MISSOURI

Dr Scott Goes to California—Gordon H Scott, Ph.D., associate professor of histology, Washington University School of Medicine, St. Louis, has been appointed professor of anatomy at the University of Southern California School of Medicine, Los Angeles.

New Health Center—A new health center will be erected in Independence with the assistance of federal funds. Examination rooms, x-ray and dental clinics will be on the first floor and the administrative section with facilities for the director, visiting nurse and sanitary division. The laboratory and sterilizing room will occupy quarters on the second floor and the assembly room will be in the basement. The city of Independence has bought the site, and the cost of \$48,000 for building and equipment is being provided by the war public works section of the federal works agency.

Head of Red Cross Midwestern Area—Dr Howard B Mettel, chief of the bureau of maternal and child health of the Indiana State Board of Health and acting director of the division of services for crippled children in the state department of public welfare, Indianapolis has been appointed director of medical and health service of the Midwestern Area of the American Red Cross with headquarters in St. Louis, effective October 1. Dr Mettel has also been assistant professor of pediatrics and assistant in medical economics and postgraduate instructor at the Indiana University School of Medicine, Indianapolis.

NEW YORK

Lecture on War Medicine—The Medical Society of the State of New York announces a special lecture on war medicine and surgery for a joint meeting of the Onondaga County Medical Society and the Syracuse Academy of Medicine in Syracuse, October 20. Dr Jacques W. Minnec, New York, will discuss "Early Treatment of War Wounds with Emphasis on Prevention of Deformities."

New York City

Tests Required Annually—Hunter College started very examinations of its 4000 pupils in September in compliance with a recent resolution of the board of higher education requiring annual x-ray and serologic tests for all students in the city colleges. Upper freshmen, upper sophomores and upper juniors are now being examined in the medical offices of the college. The rest of the student body will be given x-ray examinations in February.

Assistant Dean Appointed at Columbia—Anna E. Severinghaus, Ph.D., associate professor of anatomy at Columbia University College of Physicians and Surgeons, has been appointed assistant dean of the college. Dr Severinghaus received his Ph.D. at Columbia in 1927. He had been assistant in zoology there from 1916 to 1927 and from 1919 to 1920 when he became instructor at Pekin Union Medical College. He subsequently served as assistant professor and dean of the premedical school, joining the Columbia staff again in 1927.

Dr L'Esperance Awarded Clement Cleveland Medal—Dr Elise Depew Strang L'Esperance, a founder of the Kate Depew Strang Cancer Prevention Clinic of the New York Infirmary for Women and Children and associate commander of the Women's Field Army of the American Society for the Control of Cancer, has been presented with the Clement Cleveland Medal, awarded annually by the New York City Cancer Committee "for outstanding contributions to cancer control work." The medal was presented at a joint dinner of the American Society for the Control of Cancer and the New York City Committee, September 24. Dr L'Esperance and Miss Kate Strang, her sister, founded the Strang Cancer Prevention Clinic in 1933 with a gift of \$30,000 in memory of their mother. Since then one more cancer prevention clinic has been established at the New York Infirmary for Women and Children and three more at the Memorial Hospital for Cancer and Allied Diseases.

Health Laboratory Observes Fiftieth Anniversary—The city department of health announces the completion of fifty years service of its laboratory, which, according to the *New York Times* was also the first laboratory regularly maintained for biologic diagnosis by any public agency. A feature of the anniversary celebration is an exhibit of newspaper reports on an epidemic of cholera which was responsible for the foundation of the laboratory in 1892. The late Dr Hermann M. Biggs who was designated chief of bacteriology and disinfection on Sept. 13, 1892, persuaded the city to appropriate funds for a laboratory to combat the cholera. The laboratory was quickly installed in a few rented rooms on the third floor of a brick house at 42 Bleeker Street and was considered an anticholera station. Under Dr Biggs and later under the late Dr William H. Park the New York laboratory was maintained to fight other communicable diseases, developing into the William H. Harkness Park Laboratory.

School Programs Adapted to Physicians' Recommendations—The city department of health has during the past year assumed new responsibility for the control of special programs in schools for orthopedic cardiac and under par children in the elementary schools serving as an approving agency for changes in the regular school routine for children with physical defects. The department will attempt to interpret to teachers recommendations from physicians will observe the certain adjustments of children on special school programs and will keep the physicians informed of these adjustments. The programs in the elementary schools for orthopedic cardiac and under par children can now be planned around the specific recommendations of the physicians who are treating the chil-

dren. Under a setup whereby the schools are prepared to adapt their programs, children will be excused from the regular physical training programs for a substitute period of study or rest, if necessary, the luncheon period will be lengthened by fifteen or thirty minutes, and children will be provided with two sets of books, one to be kept in the home, thus making it unnecessary for the child to carry books to and from the school. Children with an intelligence quotient above 75 who are unable to come to school will be given home instruction if their physical condition permits. The city department of health announces that these adaptations of the school program are at the service of the private and clinic physician, who may prescribe them for his young patients as readily as he does a medication, a diet or a home routine for rest. Recommendations for the under par child will be made on the regular school health referral form. These forms may be obtained from the Bureau of Child Hygiene, 125 Worth Street.

OKLAHOMA

Changes in the Faculty—The state medical journal announces the following resignations from the faculty of the University of Oklahoma School of Medicine Oklahoma City: Irvin S. Danielson, Ph.D., assistant professor of biochemistry, to join the staff of Lederle Laboratories; Carl A. Bunde, Ph.D., instructor of physiology to accept a similar position at Baylor University School of Medicine; and Irwin C. Winter, Ph.D., assistant professor of pharmacology, to join the staff of the Council on Pharmacy and Chemistry of the American Medical Association. Alton C. Kurtz, Ph.D., instructor in physiologic chemistry, University of Pennsylvania School of Medicine Philadelphia has been appointed assistant professor of biochemistry at Oklahoma.

PENNSYLVANIA

Dr Stewart Appointed State Health Officer—Dr Alexander H. Stewart, Harrisburg acting secretary of the state board of health since 1941, has been appointed secretary. Dr Stewart, before his appointment as acting secretary, had been serving as deputy secretary since 1939.

Rehabilitation Program for the Tuberculous—The appointment of a special tuberculosis agent on the staff of the Reading district of the state rehabilitation bureau marked the beginning of the second cooperative rehabilitation program in which tuberculosis organizations in Pennsylvania are joining with the official agencies. The first was begun in 1939. Mr. Floyd L. Kefford, Philadelphia is the agent. State and local health groups are participating in the program.

Pittsburgh

Lecture on Tropical Diseases—Dr Eugene R. Kellersberger, New York, executive secretary of the American Mission to Lepers and formerly a medical missionary in Belgian Congo, Africa delivered a lecture at the Mellon Institute, October 9, under the auspices of the University of Pittsburgh School of Medicine. The subject of the lecture was "Twenty-Four Years Experience with Tropical Diseases."

New Psychiatric Hospital—The Western Pennsylvania Psychiatric Hospital has been opened on the campus of the University of Pittsburgh. The new institution will offer treatment, care and welfare of patients, research and teaching. The new unit will form a part of the medical center at the University of Pittsburgh consisting of the medical school, the Falk Clinic and Presbyterian, Women's, Eye and Ear, Municipal and Magee hospitals. Accommodations have been provided for 250 patients. Eight floors have been set aside for the care of psychotic adults and children. The hospital will function with other institutions under the control of the department of welfare in investigating clinical and laboratory problems and therapy and will eventually take a prominent part in the training of physicians for advancement in the state service, according to the *Pennsylvania Medical Journal*.

VIRGINIA

Changes in the Faculty—Dr Henry B. Mulholland, professor of practice of medicine at the University of Virginia Department of Medicine, Charlottesville has been appointed assistant dean. Other changes include the promotion of Dr. Samuel A. Vest Jr. to professor of urology and the retirement of Dr. Robert B. Bean as professor of anatomy.

Institute on Health in Industry—An institute on health in industry was held in Richmond, September 24, for employers of labor, personnel directors, physicians, nurses and organized labor, under the auspices of the committee on industrial health of the Medical Society of Virginia. The speakers included

Dr Millard C Hanson, Richmond, "Services of the City Health Department to Industrial Plants" Dr William L Weaver, Richmond, "Full Time Medical Services in Industry", Dr Fred J Wampler, Richmond, "Medical Service for the Smaller Plant," and Dr James G Townsend, Bethesda, Md "Importance of Industrial Health in War Effort" William Kirk, Ph D, manager, dye works E I du Pont de Nemours and Co, Pennsgrove, N J, addressed the dinner meeting One feature of the program was a discussion of the "Cost of Ill Health in Industry"

WEST VIRGINIA

Committee to Conserve Vision—Dr Richard O Rogers, Bluefield, president of the West Virginia State Medical Association, recently appointed a committee on conservation of vision composed of Drs Virgil E Holcombe Charleston, chairman, Welch England Parkersburg and Raymond A Tomassene, Wheeling The purpose of the committee is to cooperate with the National Society for the Prevention of Blindness and the committee on conservation of vision and prevention of blindness of the American Medical Association in matters which pertain to the conservation of vision in West Virginia

GENERAL

Meeting Suspended—The American Association for the Advancement of Oral Diagnosis has postponed its annual meeting on account of the present emergency The meeting was to be held in Boston November 12-13 H Justin Ross, D D S, New York, is the secretary

Examination in Pediatrics—The American Board of Pediatrics announces that a written examination will be held locally throughout the country on February 12 under a monitor Oral examination will be held on March 27-28 in St Louis and on April 24-25 in New York The closing dates for these examinations will be on December 1 for St Louis and on January 1 for New York

Rocky Mountain Medical Conference Canceled—The executive committee of the Rocky Mountain Medical Conference has by unanimous vote directed that the fourth biennial meeting of the conference originally scheduled for May 19-21 at Albuquerque N M be postponed indefinitely on account of war conditions The current organization of the conference will be retained subject to further advice from the continuing committee, and current funds of the conference will be invested in U S war bonds as far as is practicable

Campaign to Control Cancer—A course in cancer control measures was begun on September 14 at Bar Harbor, Maine, under the auspices of the American Society for the Control of Cancer The training is to qualify the women, who represent 225,000 volunteer workers as officers of the women's field army, to educate the public Women completing the course are expected to organize similar schools in each state Another course was held in New York September 21-25 According to the New York Times, the complete war service program to be organized in each community is to function through a health education unit, a medical aid unit and a hospital unit

New Journal of Biochemistry—The *Archives of Biochemistry* is a new publication announced by the Academic Press, Inc, 125 East Twenty-Third Street, New York The first issue will appear about the middle of October Two volumes are planned a year, the cost of each volume to be \$5.50 The editorial board is composed of Moses L Crossley, Ph D, American Cyanamid Company, Bound Brook, N J, Ross A Gortner, Ph D (deceased) University of Minnesota, Fred C Koch, Ph D, Armour and Company, Chicago, Clive M McCay, Ph D, Cornell University, Ithaca, N Y, F F Nord, Ph D, Fordham University, Frits W Went, Ph D, California Institute of Technology, Pasadena, Calif, and Chester H Werkman, Iowa State College, Ames

Association of American Medical Colleges—The fifty-third annual meeting of the Association of American Medical Colleges will be held in Louisville, October 26-28, under the presidency of Dr Loren R Chandler, San Francisco The program will include the following

Dr Hugh R Leavell, Louisville, Coordinating Program of Health Hospital and Medical School in a Municipal University
Dr Edwin Cowles Andrus, Baltimore, Medical Research in Wartime
Dr Harold S Diehl, Minneapolis, The Relationship of the Procurement and Assignment Service to Medical Education
Dr Allen O Whipple, New York, A Study of the Results of the Examinations in Anatomy by the American Board of Surgery
Dr Maurice H Rees, Denver, Finger Printing of Medical Students
Dr S Spafford Ackerly, Louisville, The Teaching of Psychiatry to Undergraduate Medical Students
Dr Russell M Wilder, Rochester, Minn, Teaching of Nutrition

American Public Health Association—The seventy first annual meeting of the American Public Health Association will be held in St Louis, October 24-30, under the presidency of Dr John L Rice, New York The session will be held in the Municipal Auditorium The Ninth Institute on Public Health Education will be conducted on October 24-27 in connection with the national meeting There will be fifty four members on the faculty of the institute to carry out discussions on a wide range of public health topics The meeting of the association will be presented in sections Included among the many speakers on the program will be

Dr Victor E Levine, Omaha, Recognition of Vitamin Deficiencies in Human Beings
Dr Frederick W Jackson, Winnipeg, Man, Vaccination Against Incephalitis
Icie Macy Hoobler, Ph D, Detroit, Protein in the Diet of Man
Dr Carl M Peterson, Chicago, The Training of the Physician
Dr Kenneth T Moxey, Baltimore, The Hypothetical Relationship of Water Supply to Cholera
Dr Harry D Kruse, New York, Nutritional Needs of American Youth
Dr Leroy U Gardner, New York, Physiologic Response to Magnesium Dust
Dr Albert S McCown, Washington, D C, First Aid Instruction in Relation to Health Education

There will be symposiums on splints, industrial hygiene and war training of industrial hygiene personnel, water and milk borne infections, tuberculosis, nutritive values of dried and dehydrated fruits and vegetables, chemical and engineering methods in industrial hygiene, respiratory diseases and environmental sanitation At the first general session announcement will be made of the winner of the Sedgwick Memorial Medal Meetings at the same time will include the American Social Hygiene Association Conference of Municipal Public Health Engineers and Conference of State Sanitary Engineers, Conference of State and Provincial Public Health Laboratory Directors, Illinois Conference on Public Health and Illinois Public Health Association

LATIN AMERICA

Course in Internal Medicine—Dr George E Burch, instructor of medicine Tulane University of Louisiana School of Medicine, New Orleans, conducted a graduate course in internal medicine and cardiovascular diseases at the Hospital Santo Tomas, Panama City, in August The program consisted of ward rounds, consultations, an introductory course in cardiology and evening lectures which were given in the Gorgas Memorial Institute The course was given at the invitation of the government of Panama

Polio myelitis Closes Schools in Havana—Health authorities on September 28 ordered primary schools in Havana and Marianao, Cuba, closed as infantile paralysis cases continued to increase according to the New York Times No official figures were issued but the local press has reported several deaths in Havana it was stated Since the majority of the cases are among children under 10 years of age, only the primary schools are now affected However, a number of private schools and higher grade schools have already closed voluntarily, the Times said It was further reported that schools in several districts of the island have been suspended during the past few weeks, and public concern is growing over the spread of the disease

FOREIGN

Prizes Awarded—The honorary medal of the Royal College of Surgeons of London has been awarded to Lord Nuffield in recognition of his service in "assisting the improvement of natural knowledge and of the healing art and of his many liberal acts and distinguished labors inspired by the desire to advance the science and practice of medicine and surgery" Science reports that this medal was instituted one hundred and forty years ago and this is the nineteenth occasion on which it has been awarded The Gilbert Blane Medal of the Royal Navy was presented recently to Surg Comdr Edward Rex Pascoe Williams for his original work on blast effects in warfare This medal was founded in 1830 by Sir Gilbert Blane a physician known for sanitary reforms in the navy and for successful measures for the prevention of scurvy It is awarded annually to a medical officer in the Royal Navy for "skill, diligence, humanity and learning the exercise of professional duties" The Moxon Medal of the Royal College of Physicians of London has been awarded to Prof Leonard G Parsons, Birmingham, England for his observation and research in clinical medicine, especially in pediatrics The Weber Parkes Prize was given to Prof Graham S Wilson, London, England, for his work on tuberculosis, according to Science

The Increase of Tuberculosis

In a discussion in the House of Lords on the treatment of tuberculosis Viscount Dawson (physician) said that there was a decline in the mortality of tuberculosis from 90 per hundred thousand persons ten years before the war to 60 in 1938, which was no mean achievement. The mortality went up considerably in the first year of the war and continued to rise in the second year. The total increase was 13 per cent. A more obvious feature of the situation was the selective character of the infection among different classes. There was a tendency for increased infection among young women and young children, particularly with regard to tuberculous meningitis. But on the whole tuberculosis was under control. As a large proportion of cattle were tuberculous it would be wise to pasteurize milk. The medical profession had been crying for organized compulsory pasteurization for years but previous governments had been stiff-necked, and the result was that pasteurization was patchy—in some boroughs it was good in others bad and in country districts most of the milk drunk was raw. The opportunities for contracting tuberculosis were greater under the strain of war. The chief difficulty was that it was common for infected persons to have vague symptoms or none at all. Mass roentgenography would make a considerable advance in early diagnosis.

For the government Lord Snell said that the position was no worse than it was a year ago. There was need for the immediate enrolment of 1,200 nurses for work in sanatoriums for the tuberculous. It had been repeatedly stated that this nursing involved no greater risk than nursing in other hospitals. The ground lost was due to war conditions which the Ministry of Health and the doctors could not control. The minister of health shared in the anxiety felt regarding the new encroachments of tuberculosis and would use every means to deal with the situation.

Advice to Students About to Join the Medical Corps

In *University College Hospital Magazine*, a well known surgeon, Brigadier E. M. Cowell, gives some advice to medical students who are about to join the Army Medical Corps. He reminds them that this is total war. Before they can treat soldiers they should know about the composition of military units, vehicles and weapons. They should learn how to handle weapons in the Home Guard. They may be able to save lives of more soldiers by a practical knowledge of camouflage sand-bagging or the actual use of weapons than by carrying out ordinary medical duties. In modern war there is no such thing as a front line with safe rear areas. Paratroops may descend anywhere and tanks cut communications at any time. By the Geneva Convention doctors are allowed to defend themselves and their patients, and the best defense may be attack. In modern war there is no such thing as a specialist noncombatant. The most important link in the medical lines of communication is the regimental medical officer. During preparation and training it is his duty to keep officers and men fit. He takes part in the life of the unit and gets to know every one of the eight hundred odd men, treats minor ailments and supervises all hygiene. In battle it is said that a good medical officer is worth two hundred rifles. Soldiers fight better when they have confidence in him.

Treatment of Rupture of the Urethra

At the Section of Urology of the Royal Society of Medicine Mr. Clifford Morson, who opened a discussion on rupture of the urethra, pointed out that this was the most serious of all injuries of the genitourinary tract, not because of the immediate mortality, which was negligible, but because of the subsequent ill health. In view of the war, one type of laceration of the urethral mucous membrane was of particular importance. In a comminuted fracture of the pubic arch due to a war wound there is much danger that a spicule may be subsequently detached and penetrate the urethra. This complication may occur some years after the fracture has united. Thus in one case micturition had been normal ever since fracture of the pelvis by a piece of shell in the last war. In 1925 the soldier was suddenly seized with pain and retention of urine. The catheter was blocked by what seemed a calculus, but roentgenograms showed a bone spicule in the membranous urethra. Such a complication could be prevented by removing all fragments in treating a gunshot wound of the pelvis.

The diagnosis of complete rupture is usually made clear by retention of urine and bleeding from the urethra. In incomplete rupture a few drops of blood may appear at the meatus followed by blood stained micturition. On no account should a catheter be passed for diagnostic purposes, it would damage the mucous membrane. If there is any doubt as to whether the urethra is completely ruptured the urethroscope is the only instrument which should be used. In every case of suspected injury of the urethra the pelvis should be roentgenographed to exclude fracture.

Treatment varies according to whether the rupture is complete or incomplete. For the latter it is necessary only to confine the patient to bed for a few days, provided the pelvis is not fractured. Instrumentation is entirely contraindicated. If a large hematoma forms in the perineum a small incision may be necessary to evacuate it. Urethroscopy is necessary every six months to study the formation of scar tissue. After a year the degree of stricture and how often dilation will be required can be determined.

In complete rupture the urine must be diverted as soon as possible. A self-retaining angular tube must be inserted suprapubically into the bladder by the trocar and cannula technique. About the third day, when shock has passed off, the torn ends of the urethra may be joined. The closure of the suprapubic fistula does not occur until healing of the urethra is complete. A period of one or two months. During this time metal bougies must be passed weekly. The patient will have a stricture for the rest of his life, and periodic dilation will be necessary.

No matter what the technique the ultimate results are uniformly bad. In many cases the scarring is so extensive that micturition is impossible and the patient is condemned to permanent cystostomy. In other cases frequent dilation, supplemented by internal urethrotomy, is necessary.

Maternity and the War

Addressing the conference of the National Association of Maternity and Child Welfare Centers, the minister of health, Mr. Ernest Brown urged that mothers should take full advantage of the fruit juices and cod liver oil available for young children through the welfare centers. Expectant and nursing mothers should also see that they get their extra rations and use all of them themselves. Only too often mothers endangered their own health and the growth of their babies by giving part of their rations to other members of the family. The babies born in emergency maternity homes set up under the war evacuation scheme numbered 57,000. With the recent increase in the birth rate the demand for midwives was greater than ever. The minister appealed to all trained midwives to stay in the profession or return to it.

BUENOS AIRES

Aug. 30, 1942

National Institute of Nutrition

The National Institute of Nutrition of Buenos Aires was established in 1928 as a municipal branch of the Rawson Hospital and was made independent of the hospital in 1938 and transformed into a national center. Dr. Pedro Escudero is the director. The work of the institute includes biologic, sociologic and economic research on nutrition, education on nutrition and social care of the people. It has six departments. The medical department has a polyclinic with offices for consultation on specialties and clinics and wards for surgery, radiology and kinesiology. It also has laboratories for clinical and pharmaceutical work. Patients who cannot pay for drugs may have them free of charge. The department of nutrition is in charge of the clinic of nutritional diseases, of a section for social and economic information of the department, of a center for free distribution of mother's milk, of the dispensary and of the care of gardens for children. The research center includes the departments of microbiology, microscopy, biologic and bromatologic chemistry and dietetics. The center for education on nutrition instructs the public through the press, radio, moving pictures, exhibits and lectures. The technical center includes the National School for Dietitians and a two year course for physicians who wish to specialize in nutrition. The National School for Dietitians, founded in 1935, gives a diploma to those who complete a three year course on nutrition and dietetics. A requisite for entering the school is to be a graduate from a national college or to have a B.S. diploma. There are also some abbreviated courses which enable the students to a diploma of auxiliary dietitian. There are also courses for nurses. The *Ateneo de Clinica de la Nutricion* and the *Asociacion Argentina de Dietologia* are two organizations under the auspices of the institute. The former is an association of physicians who specialize in nutrition whereas the latter is constituted by physicians, dietitians and auxiliary dietitians.

Dr. Pedro Escudero recently published a book, "La Politica Nacional de la Alimentacion en la Republica Argentina," which was edited by the Instituto Nacional de la Nutricion. The last part of the book contains the report of some of the research carried on by the institute on the nutritional conditions of the population of Buenos Aires as seen from medical, social and economic angles. There are also chapters on the means actually used to improve the nutritional conditions of the people as well as for preventing and controlling nutritional diseases in the country.

Transmission of Equine Encephalitis to Man

Dr. R. Cibils Aguirre, a pediatrician and director of public aid of Buenos Aires, recently directed attention to the transmission of equine encephalitis to man. Dr. Valdez of Cordoba and his collaborators reported several cases of encephalitis in children which were coincident with an epidemic of encephalitis in horses. The authors have observed 36 cases. They have sent some material for study to the Instituto Bacteriologico Nacional. Drs. Hanon and Bardeci of Buenos Aires have seen about 20 cases in the city, and the Instituto Bacteriologico Nacional has made a bacteriologic study of these cases, but the results have been negative. Professor Rosenbusch of the Facultad de Veterinaria of Buenos Aires in 1934 found that the virus of equine encephalomyelitis was similar to the accidental type but was less virulent. Several epidemics of encephalomyelitis in horses have been observed in the course of the last few years. The greatest focus of infection has been in Buenos Aires; other foci were in parts of Entre Rios, Santa Fe, Cordoba, San Luis, La Pampa and Rio Negro.

MEXICO

(From Our Regular Correspondent)

Aug. 30, 1942

Graduation at School of Public Health

Doctors and nurses who finished a postgraduate course on epidemiology and public health administration and public nursing during the first semester of the year received their diplomas from Dr. Victor Fernandez Manero, federal director of health, in the auditorium of the Institute of Tropical Diseases. Twelve doctors of the Supervisors' General Office of the Federal Department of Health who received a certificate of public health and epidemiology will leave for their respective zones in the country, and twenty-two public health nurses who finished the course left for their own jurisdictions.

The first Institute of Public Health Education was held in the School of Public Health and Hygiene. Twenty-eight health officers, one from each state health organization, attended lectures and seminars which were in charge of well known professors and specialists in different fields of public health, hygiene and publicity.

Prophylaxis of Endemic Gout

A recent decree signed by President Avila Camacho regulates the prophylaxis of endemic gout in Mexico. Through different surveys carried out by public health authorities and private institutions the goutous zones have been limited. In some of those zones, especially in the states of Hidalgo, Michoacan, Puebla and Guanajuato, gout is quite prevalent. Simple gout in Mexico is called *boeco*, *papera*, *huelic*, *prapda*, *quebradura*, *cuen huchuecho* or *quesclapovalnati* in the different goutous regions. In accordance with the law a goutous zone is that in which 20 per cent of the inhabitants present gout in any degree. In such zones only iodized salt should be used for domestic purposes besides other measures such as iodizing water supplies. Any person or firm dealing with salt must iodize it. The penalties for not accomplishing such orders will be from progressive fines to permanent closure of establishments. The federal Department of Health is responsible for the enforcement of such regulations.

Thomas Parran Visits Mexico

Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, attended the Interamerican Conference on Agriculture as a counselor. He was declared a guest of honor of the Federal Department of Health and was received by President Avila Camacho and by the National Academy of Mexico. Dr. Parran visited the Institute of Tropical Diseases, the School of Hygiene and Public Health, the tuberculosis sanatorium in Huipulco, the Institute of Hygiene, the Central Laboratories and the Army Hospital. He inspected the malaria works in the state of Morelos and other services under the control of the Federal Department of Health and the Secretariat of Public Assistance.

New Officers of the Mexican Pediatric Society

At the last meeting of the Mexican Society of Pediatrics, the following officers were elected: president, Dr. Demofilo Gonzalez; vice president, Dr. Rigoberto Aguilar P.; secretary, Dr. A. Elisa Machain; and treasurer, Dr. Ernesto Gonzalez Tejeda.

Marriages

ROSCOE LEGRAND WALL, JR., Winston Salem, N. C., to Miss Florence Emma Delaney in Glenside, Pa., recently.
LEON J. WITKOWSKI, La Porte, Ind., to Miss Roberta Vacheront in Chicago, July 11.
EVERETT H. BAKER, Louisville, Ky., to Miss Mildred Smith of New Albany, Ind., July 6.

Deaths

Harry Myrrel Stewart of Johnstown, Pa., Jefferson Medical College of Philadelphia, 1905, specialist certified by the American Board of Radiology, Inc., member of the American Roentgen Ray Society, the Radiological Society of North America, Inc., and the American College of Radiology, fellow of the American College of Physicians, president of the Cambria County Medical Society in 1920 and the Pennsylvania Radiological Society in 1918, served as a captain in the medical corps of the U S Army during World War I, for many years chief of radiology in the Memorial, Mercy and Lee hospitals, aged 66, died, August 28

Donald Miner of New York, University of Vermont College of Medicine, Burlington, 1906, member and past president of the Medical Society of New Jersey, past president of the Society of Surgeons of New Jersey, fellow of the American College of Surgeons, was awarded the Croix de Guerre from the French government and the Distinguished Service Cross for his service during World War I, for many years on the staff of the Christ Hospital Jersey City, aged 58, died, September 13, at Amherst, N. Y.

Hugh Duncan McGaughey of Joplin, Mo., University of Kansas School of Medicine, Kansas City, Kan., 1906, specialist certified by the American Board of Radiology, Inc., member of the Radiological Society of North America, Inc., served overseas as a captain during World War I, retired lieutenant commander, U S Naval Reserve, treasurer of the Jasper County Medical Society, aged 61, on the staff of the Freeman Hospital and St John's Hospital, where he died, August 13, of coronary occlusion

Wilbur Samuel Hamilton of San Antonio, Texas, Hahnemann Medical College and Hospital, Chicago, 1895, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900, specialist certified by the American Board of Radiology, Inc., member of the American Roentgen Ray Society, the Radiological Society of North America, Inc., and the American College of Radiology, past president of the Bexar County Medical Society, aged 70, died, August 27

Fayette Harding Baldwin, Bloomington, Wis., Wisconsin College of Physicians and Surgeons Milwaukee, 1909, member of the State Medical Society of Wisconsin, past president of the Grant County Medical Society, served as a lieutenant in the medical corps of the U S Army during World War I, served as director of the school board of Bloomington, aged 57, died August 22 in the Columbia Hospital, Milwaukee, of ulcerative colitis and pulmonary embolism

William Clinton Finch, Los Angeles, University of Louisville (Ky.) Medical Department, 1897, member of the California Medical Association formerly director of the tuberculosis division and the communicable disease control division of the city health department, joined the U S Army and served in the Philippine Islands and during the Boxer Rebellion in China major in the medical corps of the U S Army Reserve, aged 69, died, August 10

Charles Austin Groves, East Orange, N. J., New York Homeopathic Medical College, New York, 1881, formerly member of the board of medical examiners, one of the founders of the Homeopathic Hospital of Essex County, now known as the East Orange General Hospital, where he was a member of the board of trustees and on the consulting staff, aged 91 died August 16, at his summer home in Craigville, Mass.

William Johnson Matthews, Johnson City, Tenn. College of Physicians and Surgeons Baltimore 1892 member and formerly vice president of the Tennessee State Medical Association, past president of the Washington County Medical Society, for many years served as city physician, a founder and for many years president of the Appalachian Hospital aged 75, died, August 28, of coronary thrombosis

Frederick Mueller of Chicago, Medizinische Fakultät der Universität Wien, Austria 1896, professor emeritus of orthopedic surgery at Loyola University School of Medicine formerly professor of orthopedic surgery at the Milwaukee Medical College, on the staffs of St Mary's Hospital, Milwaukee and the Columbus Hospital, aged 71, died September 10, at Hendersonville, N. C., of coronary thrombosis

William Homer Strahan of Covington, Ky., College of Physicians and Surgeons, Memphis, Tenn., 1907 served as a captain in the medical corps of the U S Army during World War I and was associated with the U S Public Health Ser-

vice in Washington, D. C., at one time connected with the Veterans Bureau at Cincinnati, aged 56, died suddenly, August 19, of coronary thrombosis

Otto Lewis Muench, Washington, Mo., Miami Medical College, Cincinnati, 1887, member of the Missouri State Medical Association, served in the medical corps of the U S Army during World War I, formerly U S Pension Examining Surgeon, member of the school board, at one time city physician and recorder of vital statistics for Franklin County, aged 80, died in July

Benjamin Joseph Boyd, Jamaica, N. Y., New York Homeopathic Medical College and Flower Hospital, New York 1915, member of the Medical Society of the State of New York, served as a first lieutenant in the roentgenologic branch of the Cornell Medical Unit during World War I, served as school physician, aged 54, died, August 6, in the Mary Immaculate Hospital

Remaldo Vinton Ellis of Ketchikan, Alaska, Willamette University Medical Department, Salem, Ore. 1912, past president and vice president of the Alaska Territorial Medical Association, fellow of the American College of Surgeons formerly associated with the U S Public Health Service, on the staff of the Ketchikan General Hospital, aged 53, died, August 10

Lawrence Lee Washburn of Benton, Ky., University of Louisville Medical Department, 1907, past president and secretary of the Marshall County Medical Society, president of the Southwest Kentucky Medical Association in 1920, served in the medical corps of the U S Army during World War I, aged 60, died, August 6, in the Illinois Central Hospital, Paducah

George Le Roy Wissig, Baltimore University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1920 member of the Medical and Surgical Faculty of Maryland on the staffs of the West Baltimore General, Maryland General Bon Secours and St Agnes' hospitals, aged 44, died August 12, of coronary thrombosis

Charles Peter Frantz, Burlington Iowa, Northwestern University Medical School, Chicago, 1900, fellow of the American College of Surgeons, on the staffs of the Burlington, the Mercy and St Francis hospitals, oculist and aurist Chicago, Rock Island and Pacific Railway aged 73, died August 21, of embolism of the left lung

Samuel Evans Watkins, Washington, D. C., Georgetown University School of Medicine, Washington, 1892 member of the Medical Society of the District of Columbia demonstrator of dermatology and genitourinary diseases at his alma mater from 1892 to 1896, aged 71, died, August 19 of myocarditis and hemorrhagic nephritis

Harvey Milton Griffith, Conemaugh, Pa., Western Reserve University Medical Department Cleveland, 1885 member of the Medical Society of the State of Pennsylvania, aged 81, died, July 9 in the Conemaugh Valley Memorial Hospital, Johnstown, of acute retention of urine and benign hypertrophy of the prostate

Thomas Ahern Shaughnessy, New York, University of Vermont College of Medicine, Burlington 1905 was a major in the medical corps of the U S Army during World War I, serving in France and with the Army of Occupation in Germany aged 64, died, August 26, in the Veterans Administration Facility

Ross H. Speer of Vandergrift, Pa. Western Reserve University Medical Department, Cleveland 1887 for many years a member of the school board aged 78, died, August 23 in the Allegheny General Hospital Pittsburgh of postoperative pneumonia following partial gastrectomy for carcinoma of the stomach

Frank Oldham Miller, Ellicott City, Md., University of Maryland School of Medicine Baltimore 1902, member of the Medical and Surgical Faculty of Maryland, served during World War I, aged 64, died, August 25 in the University Hospital, Baltimore, of arteriosclerosis and coronary thrombosis

Benjamin Stich, New York University and Bellevue Hospital Medical College, New York, 1911 member of the Medical Society of the State of New York, aged 57, diagnostician at the New York Post-Graduate Medical School and Hospital, where he died, August 11, of coronary thrombosis

Ladimer Joseph Blaszcak, Cleveland, Loyola University School of Medicine, Chicago 1936 member of the Ohio State Medical Association, aged 34, associate staff member of St Ann's Maternity Hospital and St Alexis Hospital, where he died, August 29, of pulmonary tuberculosis

Harry Tyldesley, Central City, Ky, Louisville Medical College, 1903, served during World War I, local surgeon for the Illinois Central Railroad, on the staff of the Muhlenberg Community Hospital, Greenville, aged 68, died, August 22, of cerebral hemorrhage and arteriosclerosis

James L. Adams, Barberton, Ohio, State University of Iowa College of Medicine, Iowa City, 1929, president of the Barberton Clinic, aged 37, died August 23 in the De Ette Harrison Detwiler Memorial Hospital, Wauseon, of injuries received in an automobile accident

William Roy Riddell @ Jackson Ohio, University of Toronto Faculty of Medicine, Toronto, Ont, Canada, 1922, past president and secretary of the Jackson County Medical Society, served during World War I, aged 45, died, August 16, in an automobile accident

Ralph Joseph Iszard, Haddonfield, N J Hahnemann Medical College and Hospital of Philadelphia, 1900, on the courtesy staff of the West Jersey Homeopathic Hospital, Camden, aged 64, died, August 27, of endocarditis, diabetes mellitus and arteriosclerosis

David Arthur Lines, New Orleans Medical Department of Tulane University of Louisiana New Orleans, 1891 member of the Louisiana State Medical Society, formerly collector of internal revenue, aged 82, died, August 21, of hypertension and coronary disease

John Lipscomb Frazer, Fitzgerald, Ga, University of Louisville (Ky) Medical Department, 1891, member of the Medical Association of Georgia served as a captain in the medical corps of the U S Army during World War I, aged 75, died, August 9

Joseph Henry Gann, Brookport, Ill, St Louis University School of Medicine, 1905, member of the Illinois State Medical Society, secretary of the Massac County Medical Society, physician and surgeon for the Illinois Central Railroad, aged 61, died, August 6

Frank L. Greenewalt, Wilmington, Del, University of Pennsylvania Department of Medicine, Philadelphia, 1888, for thirty years physician to Girard College, Philadelphia, aged 76, died August 21, in Greenville of undulant fever and arteriosclerosis

Luigi Dominick Di Stefano, Baltimore, Medical College of Virginia, Richmond, 1914, for many years medical examiner for the recruits at the local army recruiting station, aged 53, on the staff of the Franklin Square Hospital, where he died, August 15

Gasper Gaspar Mauceri, Brooklyn, Regia Università degli Studi di Roma Facoltà di Medicina e Chirurgia Italy, 1941, aged 25 intern at St Catherine's Hospital where he died, August 14, of chronic glomerulonephritis, uremia and hypertension

Charles B Stewart, Huntington Texas, Memphis (Tenn) Hospital Medical College, 1900, member of the State Medical Association of Texas, president of the Angelina County Medical Society in 1931, aged 63, died recently in a hospital at Lufkin

Patrick J Brannon @ Denison, Iowa, Sioux City College of Medicine, 1904, at one time assistant to the chair of dermatology at his alma mater, physician and owner of the Denison Hospital, aged 66, died, July 11, of coronary occlusion

Marvin E Nuckols @ Richmond, Va, University College of Medicine, Richmond, 1897, formerly lecturer and demonstrator of operative surgery and clinical assistant to the chair of clinical surgery at his alma mater, aged 65, died, July 21

Frederic Joseph Shoop, Utica, N Y, College of Physicians and Surgeons, New York, 1883, member of the Medical Society of the State of New York, aged 80, died, August 10 in the Masonic Home Hospital of chronic myocarditis

Frederick Eugene Traganza, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1928, on the staff of the Germantown Hospital, aged 40, was found dead, August 6, in Wildwood, N J, of acute coronary occlusion

William Arthur Campbell, Chicago, University of Toronto Faculty of Medicine, Toronto Ont Canada, 1892, for many years examiner for the Mutual Benefit Life Insurance Company, aged 71, died, August 31, of coronary thrombosis

Joseph Lynn Deitrick, Norfolk, Va, University of Maryland School of Medicine, Baltimore, 1891, member of the Medical Society of Virginia, aged 74, died, August 30, in the Norfolk General Hospital of acute coronary occlusion

James A Branyon, Fayette, Ala, Louisville (Ky) Medical College, 1892, member of the Medical Association of the State of Alabama, aged 73, died, August 19, in the Touro Infirmary, New Orleans, of carcinoma of the stomach

Alexander Watkins Terrell @ Lynchburg, Va, Hospital College of Medicine, Louisville, Ky, 1886, for many years resident physician at the Randolph Macon Woman's College, aged 81, died, August 30, of carcinoma of the colon

Frank Joseph Raterman, Fort Lorame, Ohio, Ohio Medical University, Columbus, 1907, member of the Ohio State Medical Association, served as a member of the school board, aged 64, died, August 27, of coronary thrombosis

Arthur J Brower, Holland Mich, Detroit College of Medicine, 1900, past president of the Ottawa County Medical Society, aged 66, died, August 2, in the Blodgett Memorial Hospital, Grand Rapids, of coronary thrombosis

William Delpuech, Knoxville Tenn University of Pennsylvania Department of Medicine, Philadelphia, 1884, member of the Tennessee State Medical Association, aged 84, died, August 7, at the Knoxville General Hospital

William James Chambers, Los Angeles, Jefferson Medical College of Philadelphia, 1890, served as a major in the medical corps of the U S Army during World War I, aged 77, died, August 21 of chronic myocarditis

Edward Orson Hopkins, Rochester Minn Johns Hopkins University School of Medicine, Baltimore, 1937 member of the Minnesota State Medical Association, aged 31, on the staff of the Mayo Clinic where he died, July 26

Hugh Percy Fleming, Ottawa, Ont, Canada, Queen's University Faculty of Medicine Kingston 1895, served as a captain with a hospital unit in France during World War I, aged 72, died, August 10, in Kent England

John Edward Hasson, Bath, N Y Eclectic Medical College of the City of New York, 1899 formerly served as county coroner and as a member of the board of health of Bath, aged 66 died, August 25

Leslie Watts Schwab @ Chicago, College of Physicians and Surgeons of Chicago 1896 an Affiliate Fellow of the American Medical Association, on the staff of the Jackson Park Hospital, aged 76, died, July 11

Albert Agnew Thomas @ Indianapolis, Johns Hopkins University School of Medicine Baltimore, 1908, served as a captain in the medical corps of the U S Army during World War I, aged 58 died, July 18

John McTyeire Stewart, Van Buren Ark, Vanderbilt University School of Medicine Nashville, Tenn, 1912, member of the Arkansas Medical Society, aged 57, died, August 17, in a hospital at Fort Smith

Edgar Earl Gelder, Los Angeles, University of Pennsylvania Department of Medicine Philadelphia, 1902, on the staff of the Presbyterian Hospital-Olmsted Memorial, aged 63, died, August 18, of coronary disease

Daniel M Easter, Greensburg Pa University of Pennsylvania Department of Medicine Philadelphia, 1888, member of the Medical Society of the State of Pennsylvania, aged 82, died, August 28, in Baltimore

Charles Vincent Wadlinger, Port Carbon, Pa Medico-Chirurgical College of Philadelphia 1908 served in France during World War I, aged 56, died, July 9, in the U S Naval Hospital, Philadelphia

Andrew William Dowd, Santa Monica, Calif, Rush Medical College, Chicago, 1899, at one time member of the board of education of Carbon County, Utah, aged 73, died August 29 of cerebral hemorrhage

Joseph Rodolphus Dillinger @ French Lick, Ind, Hospital College of Medicine, Louisville Ky, 1903 past president of the Indiana Academy of Ophthalmology and Otolaryngology, aged 66, died, August 16

Royal San Clare Fisher, Arcadia Ind, Hahnemann Medical College and Hospital, Chicago 1906, served as a major in the medical corps of the U S Army during World War I, aged 69, died, August 26

William Joseph Blackshear, Panama City, Fla, Kentucky School of Medicine, Louisville 1892, at one time associated with the U S Public Health Service, aged 77, died, August 19, of chronic myocarditis

Wilson Davis Baird Jr, Oklahoma City, University of Oklahoma School of Medicine, Oklahoma City, 1926, member of the Oklahoma State Medical Association, aged 40 died August 19, of pneumonia

Orlando B Pettijohn, Noblesville, Ind., Indiana Medical College, Indianapolis, 1874, member of the Indiana State Medical Association, for many years member of the school board, aged 92, died, July 24

James Irvin Plyler, Pittsburgh Western Pennsylvania Medical College Pittsburgh 1905, member of the Medical Society of the State of Pennsylvania, aged 69, died, August 12, of cerebral hemorrhage

Anthony Damas Joseph Pelletier & Lewiston, Maine, Yale University School of Medicine, New Haven, Conn., 1934, aged 36, was accidentally drowned, July 4, while on a fishing expedition at Rangely

Nelson Howard Caplan, Boston, Tufts College Medical School, Boston 1942, aged 25, intern at the Granger Municipal Hospital Washington, D. C., where he died, August 11, of acute appendicitis

Fred Harrison Bell, Long Beach, Calif., Hahnemann Medical College and Hospital Chicago, 1903 served in the medical corps of the U. S. Army during World War I, aged 65, died, August 3

Christian Herman Beyer, Milwaukee, Rush Medical College, Chicago, 1895, member of the State Medical Society of Wisconsin, aged 70, died, September 4, of cerebral hemorrhage and arteriosclerosis

Donald Laughlin MacKinnon, Inverness, N. S., Canada, Queen's University Faculty of Medicine, Kingston, Ont., 1905, aged 68, died, August 1, in the Inverness (N. S.) County Memorial Hospital

Clarence Henry Frederick & Lorain Ohio University of Cincinnati College of Medicine 1923 served during World War I, president of the staff of St. Joseph's Hospital, aged 44, died, July 14

Paul Arthur Westbrook & Columbus, Kan., University of Oregon Medical School, Portland, 1934, aged 36, was killed, August 6, when the automobile in which he was driving was struck by a train

Frank Erastus Beauchamp, Albany, Ore., Willamette University Medical Department, Salem, 1902, on the staff of the Albany General Hospital, aged 64, died, August 24, of angina pectoris

Howard B. Boone, Champaign, Ill., Northwestern University Medical School, Chicago, 1897, president of the community high school board, formerly bank president, aged 69, died, July 27

Arthur R. Heyward, Warwick, Ga., Medical College of the State of South Carolina Charleston, 1892, member of the Medical Association of Georgia, aged 71, died, August 2, of typhus fever

Thomas D. MacGillivray, Port Arthur Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1905, aged 62, died, July 11, following an explosion on a launch on Lake Shebandowien

Clinton H. Gilmer, Villa Grove Ill., Kentucky School of Medicine, Louisville, 1888, aged 76, died, August 31, in the Douglas County Jarman Hospital, Tuscola, of cerebral hemorrhage

George E. Welker, Dresden, N. Y., University of Buffalo School of Medicine 1900, member of the Medical Society of the State of New York, aged 67, died, August 24, of cerebral hemorrhage

James Dudley George, Corinth Ky., Pulte Medical College Cincinnati, 1892, member of the Kentucky State Medical Association, bank president, aged 73, died, August 26, of myocarditis

Herbert Hustis Best & West Pembroke, Maine, New York University Medical College New York 1896, aged 71, died, August 20, near Coboconk, Ont., Canada, of coronary thrombosis

Horace Gibbons Painter, Irwin Pa., Western Pennsylvania Medical College Pittsburgh 1903, died, August 14, in the Mercy Hospital, Pittsburgh, as the result of injuries received in a fall

Thomas Edward Larner, Marysville, Calif., University of Vermont College of Medicine, Burlington 1907, member of the California Medical Association, aged 58, was found dead, July 5

Clarence Morris Hatheway & West Hartford Conn., University and Bellevue Hospital Medical College New York 1903, aged 60, died, August 3, of hypernephroma with metastases

Albertus A. Cheney & Lyndonville, Vt., University of Vermont College of Medicine Burlington, 1887, at one time a druggist, aged 79, died, August 22, of chronic myocarditis

George Samuel Row & Indianapolis, Miami Medical College, Cincinnati, 1890, member of the American Academy of Ophthalmology and Otolaryngology, aged 75, died, July 8

Charles A. Critchlow, Grand Rapids, Mich., University of Michigan Homeopathic Medical School Ann Arbor 1894, aged 72, died, July 28, in the Blodgett Memorial Hospital

Luther M. Abbott, New Castle, Va., Baltimore Medical College 1898, member of the Medical Society of Virginia, aged 72, died, August 16, of hypertension and heart disease

John Jacob Knoll, Vermilion, Alta., Canada, McGill University Faculty of Medicine, Montreal Que., 1915, aged 61, died, July 31, in the Royal Victoria Hospital, Montreal

Daniel MacDonald, Sydney, N. S., Canada, College of Physicians and Surgeons, Baltimore 1892, served as a major during World War I, aged 81, died, July 31, in Mabou

Edward Ambrose Secoy, Orient Ohio, Physio-Medical College of Indiana, Indianapolis, 1899, formerly mayor of Darbyville, aged 67, died, August 26, of angina pectoris

Jackson Searles, York Pa., Ohio State University College of Medicine, Columbus 1925, served during World War I, aged 47, died, August 31, of acute dilatation of the heart

Nicholas E. Woessner, Huron Ohio Northwestern University Medical School, Chicago, 1893, member of the Ohio State Medical Association, aged 73, died, July 31

Walter Adjutor Maguy, Chicago, Hahnemann Medical College and Hospital, Chicago, 1912, on the staff of St. Francis Hospital, Blue Island, Ill., aged 56, died, July 18

J. Stucky Smith, Bayonne, N. J., Long Island College Hospital, Brooklyn, 1898, aged 66, died, August 20, in Germantown, N. Y., of cerebral hemorrhage

George A. Dennis & Montgomery Ala., Southern Medical College, Atlanta, Ga., 1893, formerly on the staff of St. Margaret's Hospital, aged 69, died, July 21

Howard Marshall Smith, Richmond, Va., University of Maryland School of Medicine Baltimore, 1889, also a dentist, aged 75, died, July 4, of heart disease

Charles L. Chapple, Olympia Wash., University of Minnesota College of Medicine and Surgery Minneapolis, 1898, aged 73, died, August 19, of arteriosclerosis

Orman Stafford Whitmore & Bath, N. Y., Syracuse University College of Medicine, 1934, aged 33, was killed, August 27, in an automobile accident

Marshall Lord Warrin, New York, College of Physicians and Surgeons New York, 1885, aged 83, died, July 6, at his summer home in Amagansett, L. I.

George Joseph Saylin, Los Angeles, University of Buffalo School of Medicine, 1910, aged 66, died, August 4, in the Cedars of Lebanon Hospital

Albert A. Anderson, Los Angeles, Rush Medical College, Chicago 1882, member of the Iowa State Medical Society, aged 84, died, July 27

Herbert George Finley Blair, North Gower, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1902, aged 66, died, July 10

Jeff T. Holcombe, Mineral Springs Ark. (licensed in Arkansas in 1903), member of the Arkansas Medical Society, aged 78, died, July 31

Jean Baptist Cloutier, Letellier Man., Canada, Manitoba Medical College Winnipeg, 1916, aged 52, died, August 5, of cerebral hemorrhage

Dalraddy L. Macdonald, Shawinigan Falls, Que., Canada, McGill University Faculty of Medicine, Montreal, 1912, aged 56, died, June 23

John Fred Quenzer, Chicago, Dunham Medical College, Chicago 1901, Hering Medical College, Chicago, 1904, aged 79, died, July 27

Frederick Walter Luhman & Pender, Neb., Rush Medical College Chicago, 1902, aged 63, died, August 10, of coronary thrombosis

Rolland Lee Marrett, Silver City N. Mex., University of Texas School of Medicine, Galveston, 1927, aged 44, died, August 19

Fred W. Nause, Sheboygan, Wis., Chicago Homeopathic Medical College, 1887, aged 78, died, August 18, of bronchiectasis

Charles H. Manning, Chicago, Rush Medical College Chicago, 1894, aged 71, died, August 21, of heart disease

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines" or medical devices have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

ADM Wheat Germ Oil—According to a stipulation which the Archer Daniels Midland Company, Minneapolis, signed with the Federal Trade Commission in April 1942, the following misrepresentations among others are to be discontinued in the advertising of this product: that it is a competent remedy for nervousness, lack of vitality, hay fever, or dandruff, or will prevent colds, or that the use of wheat germ oil or vitamin E produced by the solvent extracted process causes or may cause cancerous growths.

Allay—This is put out by Pickgan Labrofacts Inc., New York, which in April 1942 stipulated with the Federal Trade Commission that it would discontinue the following advertising misrepresentations: that through use of the word "pain unqualified" as to type of pain, this product normally will afford some measure of relief, or that it has any appreciable effect on persistent and frequently recurring pain, that it is safe for use and affords a new method in its field, that it begins to act in three seconds after being taken, or that it has any efficacy in preventing development of colds or is an effective cold remedy. Further, the concern stipulated that it would not publish any advertisements which do not clearly reveal that Allay should not be used in excess of the recommended dosage, since such use might be dangerous. It was provided, however, that when the labeling contains an appropriate warning, it will be sufficient if the advertisement states: "Caution: Use only as directed." This 1942 stipulation was accepted by the Commission as a substitute for one covering similar practices which the same concern had signed in June 1940. That case was abstracted in this department of THE JOURNAL, Sept. 13, 1941, page 952.

Apolene—This was sold as a remedy for rheumatism, sinusitis, hay fever, head and chest colds, bronchitis, influenza, and eczema by Claude R. Wadlington, John T. King, and G. P. Thomas, operating as Clude R. Wadlington Company, Hopkinsville, Ky. In May 1942, these persons stipulated with the Federal Trade Commission that they would discontinue these and some other misrepresentations.

Bolk—The Cal Par Corporation of New York signed a stipulation with the Federal Trade Commission in February 1942 in which it agreed to discontinue the following misrepresentations for this product: that it acts as an intestinal tonic, relieves constipation in a natural manner, or is safe to use in cases of colitis or constipation, that it will always be of benefit where symptoms of headache, nausea, dimmed eyesight, or weakness are present, that it will prevent toxins from breaking down the intestinal walls and entering the blood stream, or will forestall degenerative changes in nerves, glands, or organs, or be a safeguard against obesity. The concern also agreed to cease issuing any advertisement which failed to reveal that Bolk should not be used when abdominal pain, nausea, or other symptoms of appendicitis are present, provided, however, that the advertisement need contain only the statement: "Caution: Use only as directed, if and when the label itself bears an adequate warning about the danger in using Bolk when these symptoms are present."

Dr. McKenzie's Sanitary Health Sox—In April 1942, one David M. Conn, wholesaler of hosiery, New York, stipulated with the Federal Trade Commission that he would cease using the abbreviation "Dr." or the word "Doctor" either with or without the name "McKenzie" in the trade style for this hosiery, which use might imply that there is a physician connected with the manufacture of this product, or that the hosiery has been made under the supervision of a physician. Conn further agreed to cease using the word "Health" as part of the trade name, or as descriptive of his hosiery products, or any other implication that his merchandise has special health features capable of warding off or ameliorating disease or pain.

Dr. Merritt's Health Shoes—Because these have not been designed or made under the supervision of a physician and do not possess special scientific orthopedic or health features which are the result of medical determination or services, the Merritt Shoe Company, Inc., Boston, signed a stipulation with the Federal Trade Commission in April 1942 in which it agreed to discontinue use of the terms "Doctor," "Dr.," and "Health" from the name of its shoes.

Effervescent Seltzer and Ritz Breath Purifier—The first named of these is put out under the name of Honoroff Laboratories, Inc., Chicago, whose president is one Fred A. Honoroff. In March 1942, the concern

stipulated with the Federal Trade Commission that it would cease disseminating any advertisements which did not conspicuously reveal that the product should not be used in excess of the dosage recommended, since this might cause dependence on a drug, or result in skin eruptions, mental derangement, or collapse, and that it should not be administered to children. The stipulation provided, however, that it would be sufficient for the advertisements to warn the reader: "Caution: Use only as directed." provided that the label called attention to the dangers mentioned above. The Honoroff Laboratories, Inc., trading under a different name, Ritz Laboratories, also put out Ritz Breath Purifier and they further stipulated that in selling the latter product, they would cease representing that it prevents bad breath or destroys breath odors. In 1938, another government agency, the Food and Drug Administration, also took action against the Honoroff concern for violating the Pure Food and Drugs Act in representing on the labels of Effervescent Seltzer that this nostrum was good for stomach disorders and after-effects of excessive eating and drinking. In this connection, government chemists reported that the product was essentially a mixture of baking soda, citric and tartaric acids, with 12 per cent of acetanilid (5 grains per ounce), 28 per cent of sodium bromide and caffeine.

Fahrney Products—From Chicago, the Dr. Peter Fahrney and Sons Company puts out a number of nostrums, including Formis Alpenkrauter, Formis Magolo, and Formis Heil Oel Liniment. These three were mentioned in a stipulation which the concern made with the Federal Trade Commission in March 1942. In this, the company agreed to cease representing that the Alpenkrauter will regulate the bowels, relieve rheumatic pain, ward off disease, and beneficially affect skin eruptions; that the Magolo will neutralize acids in the stomach, or be of benefit in diarrhea due to summer complaint; and that the Heil Oel Liniment is a competent treatment for severe burns, corns, and calluses, or wounds from rusty nails, and may be used for backache with beneficial results, unless such representation is limited to the type of this disorder in which such results may be obtained. Formis Alpenkrauter was reported some years ago by the state chemists of North Dakota to contain over 14 per cent of alcohol, about 13 per cent of sugar, and a little laxative material.

Fernol Concentrate—Arthur T. Wilson, trading as the Fernol Company, Chicago, stipulated with the Federal Trade Commission in May 1942 that he would no longer represent that this product will take off weight without deleterious effects, and that he would discontinue any advertisements which failed to reveal that its continued or frequent use may result in severe gastrointestinal irritation and interference with the digestive processes, and cause dependence on laxatives. Further, he agreed that his future advertising would warn the user that "Fernol Concentrate" should not be used when symptoms of appendicitis are present, such as nausea, vomiting, and abdominal pains. The stipulation provided, however, that it would be sufficient for the advertising to contain the simple warning: "Caution: Use only as directed, if and when appropriate warning and directions for use were given on the label."

Garfield Headache Powders—In May 1942, the Garfield Tea Company, Brooklyn, stipulated with the Federal Trade Commission to discontinue any advertisements which did not clearly reveal that this product should not be used in excess of the dosage recommended, lest it cause dependence on the acetanilid which it contains, or bring on a collapse, and that it should not be taken by or administered to children. The stipulation provided, however, that the advertisements need contain only the statement: "Caution: Use only as directed, if and when the directions in the labeling contain an appropriate warning."

Muscle Rub—In May 1942, Herman H. Kronberg, trading as Muscle Rub Company, Inc., Philadelphia, stipulated with the Federal Trade Commission that in the advertising of this rubefacient, he would no longer represent that it is a new discovery, or is effective in relief of pain due to rheumatism, lumbago, neuritis, sciatica, neuralgia, or lameness, or possesses any value in excess of giving temporary relief as a mild counterirritant rub in those cases of minor pain or discomfort where use of this type of preparation is indicated. In two instances, in 1935, the Food and Drug Administration reported that it had taken action against Kronberg, then trading as Roo Mo Rub Corporation, Philadelphia, because of false claims made on the labels of an alleged rheumatism cure that he was then selling as "Roo Mo Rub." Government chemists reported that it was a mixture of alcohol (80 per cent), water, and a small amount of wintergreen oil.

Odoform—That this is valuable in the treatment of gout, rheumatism, dropsy, paralysis, skin and blood disorders, diabetes, indigestion, or kidney and bladder complaints, and that Odoform baths surpass world renowned mineral baths, or that the product when used as directed is antiseptic or prophylactic, or has sterilizing properties, are misrepresentations which James J. Bessemer, trading as Bessemer Health Products, and as Bessemer Chemical Company, Miami, Fla., agreed to discontinue in his advertising according to a stipulation which he signed in April 1942 with the Federal Trade Commission.

Oil of Salt—In April 1942, Edgar B. Minnie, F. S. and Fred D. Penn, operating as the C. A. Mosso Laboratories, Chicago, stipulated with the Federal Trade Commission to discontinue the following misrepresentations in their advertising of this product: that it possesses any hemostatic properties, is an effective relief for poisoning, or of value in treating burns except those of a minor nature, or athlete's foot, or other foot ailments, unless these are specified by name. The

Pennys further stipulated that they would no longer represent that in the experience of executives in industrial concerns Oil of Salt is the most effective first-aid that they have used or that the majority of them employ it exclusively, when such statements are not supported by facts. In addition they agreed to cease using the word Laboratories as part of their firm name unless they actually own and operate a laboratory and to stop representing, by use of the brand name Oil of Salt, or otherwise that the product possesses salt in any therapeutic amount. In two instances (in 1929 and 1930) Oil of Salt was declared in federal courts to violate the Pure Food and Drugs Act because of false and fraudulent statements in the labeling. According to government chemists' reports in these cases the product consisted essentially of luscious oil, turpentine, camphor and carbolic acid and bacteriological examination showed that it possessed no germicidal properties and only very weak antiseptic action. Recent inquiries indicate that the name of the product has been changed to Oil O Sol.

"Permanent Relief from Sinus Trouble and Asthma"—This is the title of a book sold by an Edwin W. Hirschbrook, Norfolk, Neb. In January 1942 he stipulated with the Federal Trade Commission that he would cease representing that to follow the advice given in his book will have any effect on the treatment of asthma or afford permanent relief from sinusitis.

Ro Marl—That this is an effective treatment for arthritis, neuritis, rheumatism, sciatic lumbago, gout or pain associated with these conditions was a misrepresentation which William C. Carr and Ronald Brunswick, Jr., trading as Ro Marl Company, Los Angeles, agreed to drop from their advertising in a stipulation that they signed with the Federal Trade Commission in March 1942. A similar one was signed by W. C. Jeffries of Los Angeles who operates under the name W. C. Jeffries Company, advertising agency for the Ro Marl concern. In an action brought by another government agency, the Food and Drug Administration, against the American Ro Marl Company, Los Angeles, in October 1940 because of false claims on the label, a government chemist testified that Ro Marl contained about 99 per cent of water with small amounts of potassium carbonate and the sulfate chloride hydroxide and carbonate of sodium with a trace of an organic compound such as chloramine T. This nostrum was dealt with at some length in THE JOURNAL, Sept. 12, 1936, page 894.

Sas Nak—In a stipulation signed with the Federal Trade Commission in March 1942 one Arthur T. Wilson, trading as the Sas Nak Company, Kansas City, Mo., agreed to discontinue the following misrepresentations in the advertising that the product is a cure remedy or effective treatment for indigestion, kidney, bladder, liver and stomach disorders, rheumatism, colds, influenza and skin eruptions or that it has any value in treating such conditions beyond the temporary relief that it may give by partially evacuating the intestinal tract or stimulating the flow of gastric juice. The concern further agreed to discontinue any advertisements which stated that Sas Nak should be taken regularly every day or which failed to reveal that it should not be used when abdominal pains, nausea, vomiting or other symptoms of appendicitis are present, that frequent or continued use of Sas Nak may result in dependence on laxatives and that the product contains a powerful poison, strychnine, in quantities sufficient to be dangerous to health if taken in excess of the dosage recommended. The stipulation permitted, however, that it would be sufficient warning to state in the advertisements: Caution, use only as directed, provided that the label carried an appropriate warning.

"The Philosophy of Fasting," "The Natural Method of Healing," "Return to Nature," "The Water Cure" and "The Naturopath"—These are titles of books put out by Benedict Lust of New York, operating as Health Book Service and Benedict Lust Publications. In March 1942 Lust signed a stipulation with the Federal Trade Commission. In this he agreed to cease representing that by reading and following the instructions in these volumes a person will be able to cure or relieve any ailment or disease. Lust stipulated further that he would cease representing that his health foods will cure diseases or restore organs to their proper functions and that Lust's Barley Malt Coffee is nerve building. The titles that Benedict Lust has used after his name indicate that he classifies himself largely with the osteopaths and naturopaths and he has promoted various health fads besides having had a run in with the law on more than one occasion.

Thyphenol—That this product has 5 times the killing power of carbolic acid or may be freely used on burns that as a first aid application to wounds it will arrest dangerous infections instantly that it will effectively kill germs even though diluted 400 times be effective against athlete's foot and relieve pain and that it contains no drugs are misrepresentations which are to be discontinued in the advertising according to a stipulation signed with the Federal Trade Commission in April 1942 by Robert C. Harman, trading as Carol Products Company, Columbus, Ohio.

Walker's Indian Herbs and Walker's Health Tonic—The first named product was falsely represented as a remedy for diabetes; the continued use of which would enable a patient gradually to consume less insulin and the second named one to treat stomach disorders including ulcers, clean the blood, restore action to the liver and kidneys and remove gravel or gallstones. These misrepresentations were to be discontinued as agreed by Perceville E. Walker, trading as P. E. Walker and Company, Portland, Ore., in a stipulation that he signed with the Federal Trade Commission in May 1942. According to this he was not to offer the Tonic as anything but a bitter stomachic, a mild laxative and a diuretic.

MISBRANDED COSMETICS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act and are designated C N J. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

California Nutrient Cream and Sue Sorrell Texture of Youth Cream—Jerome Tredway, New York. Shipped between June 27 and Dec. 3, 1940. Composition: both products were essentially mixtures of hydrocarbon oils, hydrous wool fat and perfume. California Nutrient Cream contained also sodium borate. The first named product was misbranded because designation nutrient cream was false and misleading; second named one misbranded because of false label claim: an aid in warding off fine lines and wrinkles. —[C N J F D C 65, January 1942]

Farr's For Gray Hair—Brookline Chemical Company, Boston. Shipped between Oct. 4 and Dec. 1, 1939. Composition: a liquid containing silver nitrate and tablets containing diamidophenol hydrochloride. Adulterated because of these poisonous or deleterious ingredients. Misbranded because label failed to warn against using this dye on eyelashes and eyebrows which use might cause blindness or to caution against use without a preliminary test for user's sensitivity to such dye. —[C N J F D C 33, May 1941]

Glo Co Hair Groom for Men—Glo-Co Company, Los Angeles. Shipped Aug. 19, 1940. Composition: essentially a mixture of alcohol and castor oil with perfumed materials. Misbranded because of deceptive claims on label or in accompanying circular such as: tones the scalp. Cleansing with Glo-Co Hair Groom is the first step that helps to restore sebaceous glands to normal action. —[C N J F D C 62, January 1942]

La Nu Hair and Scalp Vitalizer—La Nu Distributing Company, Philadelphia. Shipped between Jan. 20 and Feb. 3, 1941. Composition: essentially a mixture of ammoniated mercury, boric acid, oil of eucalyptus and hydrous wool fat. Misbranded because falsely represented as a hair and scalp vitalizer and efficacious for alopecia and falling hair. —[C N J F D C 61, January 1942]

Louise Norris Lash and Brow Coloring—Louise Norris Company, Kansas City, Mo. Shipped between Mar. 19 and Aug. 22, 1940. Composition: Formula No. 1: Prepare a solution of silver proteinate. Formula No. 2: Protecto essentially hydrous wool fat. Formula No. 3: Absorbo (or simply Absorbo) magnesium carbonate bottle marked A: a solution of 2.5 toluenediamine with sulfite and sulfate of sodium; bottle marked B: a solution of hydrogen peroxide. Ingredient 2.5 toluenediamine potentially dangerous to health if applied under conditions of use prescribed in the labeling or under such conditions of use as are customary. Treatment declared adulterated because of presence of this potential poison and because the latter a coal tar color was not from a batch that had been certified according to legal regulations. Treatment also declared misbranded because of false label claim that it conformed with all local state and federal regulations of the Food, Drug and Cosmetic Act. —[C N J F D C 32, May 1941 and C N J F D C 59, January 1942]

Mary Luckie Hair Tints—Marlu Company, Kansas City, Mo. Shipped between April 21 and June 12, 1941. Composition: included para-phenylenediamine, a poisonous or deleterious substance which might have rendered them injurious when used under customary conditions and hence adulterated. Misbranded because designation hair tint was false and misleading since these products were not hair tints but eyelash and eyebrow dyes. —[C N J F D C 58, January 1942]

Quinlan Pore Cream and Quinlan Skin Stimulant—Kathleen Mary Quinlan, Inc., Distributor, New York. Shipped between Jan. 14 and Feb. 20, 1941. Composition: Pore Cream essentially petrolatum, zinc oxide, hydrous wool fat, water and perfume. Skin Stimulant essentially alcohol, water, glycerin, perfume and coloring matter. Products misbranded because of misleading names falsely representing that they were respectively efficacious for coarse pores and texture and for stimulating the skin. —[C N J F D C 64, January 1942]

Sparkl Medicated Skin Cream, Paulette Hair Dressing and Brilliantine Roland—Sparkl Company, Brooklyn. Shipped between Jan. 24 and Sept. 11, 1940. Composition: not stated. Products declared adulterated because they consisted in part of filthy substances and had been prepared or packed under insanitary conditions. —[C N J F D C 63, January 1942]

Willat Method of Heatless Permanent Waving—Willat Production Company, San Francisco. Shipped between Jan. 1 and May 23, 1941. Composition: included ammonium hydrogen sulfide, a poisonous or deleterious substance which might have rendered it injurious if applied under such conditions of use as are customary, hence adulterated. Many consignments of this seized in coast-to-coast shipments. —[C N J F D C 51 to 57, inclusive, January 1942]

HEALTH ASPECTS OF FUEL OIL RATIONING

To the Editor—Enemy action and the greatly increased burden of the war effort have so seriously curtailed the transportation of petroleum products that households this winter can be heated only by limited supplies of fuel oil, consequently the problem of maintaining health in temperatures lower than usual is not only difficult but must be solved to prevent illness. Before the war the East Coast received about 95 per cent of its oil by means of tankers. So many of these tankers have gone down that an extremely serious dislocation in our petroleum distribution system has come about. In view of the resultant urgent necessity to share limited supplies fairly, the Fuel Rationing Division of the Office of Price Administration has drawn up a plan for the rationing of fuel oil in thirty states designated by the War Production Board. The fullest patriotic cooperation of your profession will be necessary and without doubt will be given.

Basic rations for fuel oil will be allotted householders by the Office of Price Administration through its rationing boards. This ration will be based on past consumption (adjusted for normal weather) and on the thermal efficiency of the house as indicated by a heat loss floor area formula developed and tested by top flight heating engineers. Provision will also be made for auxiliary rations to households in which illness or the infirmities of old age make necessary temperatures higher than that afforded by the basic ration.

Application for such auxiliary ration will be made to the local rationing board by the consumer. His application will have to be supported by certification by a licensed physician. In certifying, the physician should give the date, the name and address of the householder and should certify to the Office of Price Administration (1) whether the illness is of an acute or chronic nature, (2) whether it is the kind which requires higher indoor temperatures, (3) the approximate temperatures required and (4) the approximate period for which this supplemental base heat is needed. The physician may at his discretion state the nature of the illness and give any additional information which will guide the board. This certificate should be given to the applicant, who will file it with the local rationing board.

The success of the rationing plan in meeting the fuel oil emergency equitably and effectively will depend in large part on the kind of patriotism and conscientious cooperation that the medical profession has always given in times of emergency.

It is planned that advisory committees of three members, composed of two licensed physicians and the county or local health officer will be set up by the county or local medical association on request of the local rationing board. These advisory committees will function by reviewing the cases of the certificates questioned by the local rationing board when the board wishes more detailed information and professional opinion. I am sure that the medical and public health professions will cooperate actively in setting up and operating this important auxiliary advisory body.

JOEL DEAN

Director, Fuel Rationing Division,
Office of Price Administration

NOTE—The Office of Price Administration makes available the following additional information:

Families with children under 4 years of age will receive a fuel oil allowance of from 50 to 125 gallons, depending on the heating zone, in addition to their basic ration under the new fuel oil ration plan, the Office of Price Administration

announced, October 3. Intended as a safeguard for the health of small children, the supplemental allowance will permit raising the temperature in a well insulated house from 65 F, the level provided by the basic ration, to about 70 F in the space that must be occupied by children. It will not necessarily mean that the entire house can be heated to this temperature, OPA officials stated.

Specific allowances for the four zones are zone A, 125 gallons, zone B, 100, zone C, 75, and zone D, 50. Zone A includes the northernmost and coldest section of the rationed area. The other zones have progressively warmer climates.

The allowances will not be increased for families with more than one child under 4, nor will the size of the house affect the size of the allowance. The gallonage provided in the allowance is considered sufficient to heat adequately whatever space children in the household need to occupy, OPA officials pointed out. Householders will get supplemental rations for children when they register. The fact that children under 4 are living in the house will be noted on the application.

While the allowance for children is the only supplemental ration for which a blanket allowance of a definite number of gallons is provided, the rationing plan will make possible other auxiliary rations when they are needed to avert extreme hardship. Homes with sickness will be afforded additional fuel allowances as will those in which elderly persons reside. In both of these cases, however, a doctor's certificate will be required. This statement must be presented with an auxiliary ration application, which will determine the amount of fuel necessary to meet the special circumstance. However, OPA officials repeated the warning that applications for any supplemental ration will be denied to applicants who in the judgment of the local board, can reasonably be expected to convert their furnaces to coal. Only by converting to coal can householders with convertible furnaces be assured all the heat they want for comfort, OPA pointed out.

"NONSPLINTING TREATMENT OF FRACTURES OF THE ELBOW JOINT"

To the Editor—In the June 27 issue of THE JOURNAL a communication was published from Dr. D. H. O'Donoghue commenting on my article entitled 'Non-splinting Treatment of Fractures of the Elbow Joint,' which appeared in the issue of March 21.

The obvious misconception as indicated by the two chief objections to this method of treatment should be clarified. The objections are essentially that the method oversimplifies the treatment of fractures of the elbow and that anatomic reposition should be obtained.

The non-splinting treatment of fractures of the elbow is by no means an oversimplification of treatment. On the contrary, the method involves greater skill, care and time than the usual splinting method. As to the anatomic reposition it was indicated that in these fractures the fragments are difficult and frequently impossible to realign and that it is even more difficult to hold them in realignment. Fractures with fragments of sufficient size so that they can be manipulated and maintained should obviously be so treated.

This method of treatment was stimulated by two observations. First, that many treated fractures both by specialists and by general practitioners, gave seriously poor results. Second, that a number of patients with fairly extensive fractures did very well with little or none of the accepted treatment.

It was hoped that the publication of this preliminary report would stimulate clinical reports of cases treated by this method and the results obtained rather than theoretical considerations that can be decided only by scientific and unbiased experience.

Missouri June Report

The Board of Health of Missouri reports the written examination for medical licensure held at St Louis, June 4-6, 1942. The examination covered 15 subjects. An average of 75 per cent was required to pass. One hundred and seventy candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Georgetown University School of Medicine		(1938)	1
Northwestern University Medical School		(1939) (1941)	2
Graduate School of Medicine of the Division of the Biological Sciences		(1931)	1
Rush Medical College		(1942)	1
The School of Medicine of the Division of the Biological Sciences		(1938)	1
University of Chicago The School of Medicine		(1941) 2)	2
University of Illinois College of Medicine		(1941)	1
Harvard Medical School		(1937)	1
St Louis University School of Medicine		(1940) (1942) 74)	75
Washington Univ School of Medicine		(1941) 2) (1942) 76)	78
University of Rochester School of Medicine		(1939) (1941)	2
Jefferson Medical College of Philadelphia		(1941)	1
Marquette University School of Medicine		(1942)	1
University of Toronto Faculty of Medicine		(1936) (1938)	2
Regia Università di Napoli Facoltà di Medicina e Chirurgia		(1935)	1

Seventeen physicians were licensed to practice medicine by reciprocity and 2 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners on June 3 and July 25. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Arkansas School of Medicine		(1933) (1935)	
(1941) Arkansas			
Rush Medical College		(1931) Louisiana (1937)	Illinois

Colorado July Report

The Colorado State Board of Medical Examiners reports the written examination for medical licensure on July 8-10, 1942. The examination included 61 questions. Seven candidates were examined, 4 of whom passed and 3 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Harvard Medical School		(1941)	1
Osteopathy *			3
School	FAILED	Year Grad	Number Failed
Osteopathy †			3

* Licensed to practice medicine and surgery

† Examined in medicine and surgery

Nebraska June Report

The Nebraska State Board of Medical Examiners reports the written examination for medical licensure held at Omaha, June 8-10, 1942. The examination covered 10 subjects. An average of 75 per cent was required to pass. Seventy-six candidates were examined, 74 of whom passed and 2 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Creighton University School of Medicine		(1940)	12
(1941) 5) (1942) 6)			
University of Nebraska College of Medicine		(1939)	62
(1941) 2) (1942) 59)			
School	FAILED	Year Grad	Number Failed
University of Nebraska College of Medicine		(1941) (1942)	2

Three physicians were licensed to practice medicine by reciprocity and 3 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners from January 22 through May 23. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Creighton University School of Medicine		(1928)	Kansas
University of Nebraska College of Medicine		(1925)	Tennessee
University of Oregon Medical School		(1935)	Oregon
School	LICENSED BY ENDORSEMENT	Year Grad	
Yale University School of Medicine		(1936)	
Creighton University School of Medicine		(1940)	
Duke University School of Medicine		(1939)	

Tennessee March Report

The Tennessee State Board of Medical Examiners reports the examination for medical licensure held at Memphis, March 25-28, 1942. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-two candidates were examined, all of whom passed. The following school was represented:

School	PASSED	Year Grad	Number Passed
University of Tennessee College of Medicine		(1941) (1942) 21)	22

Fifteen physicians were licensed to practice medicine by endorsement from February 11 through June 5. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
College of Medical Evangelists		(1941)	Georgia
Emory University School of Medicine		(1938)	Georgia
Rush Medical College		(1937)	Minnesota
Indiana University School of Medicine		(1924) (1933)	Indiana
University of Louisville Medical Department		(1910)	Kentucky

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Food, Drug, and Cosmetic Act Shoo Fly Powders for Drunkenness Misbranded—Section 352 of the Federal Food Drug, and Cosmetic Act provides "A drug or device shall be deemed to be misbranded—(a) If its labeling is false or misleading in any particular" and "(j) If it is dangerous to health when used in the dosage, or with the frequency or duration prescribed, recommended, or suggested in the labeling thereof. Such misbranded article is liable to condemnation under section 334 'when introduced into or while in interstate commerce', or at any time thereafter," Acting under the authority of these provisions, the United States filed a libel for the condemnation of 11¼ dozen packages of 'Mrs Moffat's Shoo Fly Powders for Drunkenness' The M F Groes' Son & Co intervened as owner and manufacturer of the articles in question and the case was heard in the district court, western division New York.

The label on Shoo Fly Powders stated that they were "For Drunkenness," that they contained antimony and potassium tartrate, that "One of the Powders may be given in Beer, Coffee, Tea or any other liquid" and that "These powders are intended to be used by adults only, and should be kept from children." It was admitted that the articles in question had been shipped in interstate commerce. The intervenor first contended that the government was required to show intent to deceive and defraud. The court pointed out, however, that under the present law it is not necessary to prove intent. It was also urged that merely stating that the article is 'for drunkenness' is not sufficient to constitute an offense of misbranding. The use of the words "for drunkenness," in the opinion of the court, was the equivalent of saying that the article was a 'cure mitigation treatment, or prevention' of drunkenness.

According to the evidence Shoo Fly Powders contained on the average 32 grams of potassium antimony tartrate (tartar emetic) and no other constituents. Five physicians testified on behalf of the government, one being a pharmacologist, one an internist, one a specialist in therapeutics and two neuropsychiatrists. All had had extensive experience in their respective specialties. Each testified that antimony and potassium tartrate (tartar emetic) is not a curative for drunkenness, that it is a drug not properly usable in the treatment of drunkenness and that its use in the dosage shown on the label is dangerous to health. Each testified that the medical profession has long recognized that antimony and potassium tartrate is a drug dangerous to be administered through the mouth, that its use through the mouth has been abandoned in the teaching field, and that the standard textbooks treat it as a poison. They further stated that antimony and potassium tartrate taken through the mouth, irritates the lining of the stomach and intestine and produces injurious effects on various other organs of the body, that its effect is cumulative and that when it is taken in increased doses it causes nausea, vomiting, diarrhea and retching, that after absorption it affects the liver and kidneys, increases the heart rate and through the resulting loss of the control of the muscles of the stomach the vomitus may be swallowed, causing pneumonia. In conclusion they added that the medical profession for many years has not prescribed antimony and potassium tartrate to be taken through the mouth except as it is so used in Brown's Mixture which contains 1/70 grain (0.0009 Gm) of this drug and that its present use is almost entirely intravenously or intramuscularly as a treatment for numerous tropical diseases.

The only evidence offered by the intervenor was that given by an official of the claimant to the effect that the drug in question had been sold for upward of sixty years, that more than 50,000 of the powder packages have been sold yearly for the last ten years and that not a single case of harm or injury

had ever been reported by any one to the manufacturers. Objection was raised to the reception of this official's testimony. The court said that the testimony as to the number of packages of the powder that had been sold and the period over which it had been sold was competent. The testimony that no complaints had been received concerning the powder was held to be incompetent, however.

After referring to the data concerning antimony and potassium tartrate appearing in the U S Pharmacopeia and the National Standard Dispensary, the court said that the conclusion was inescapable both that the label on Shoo Fly Powders was false and misleading and that the drug was dangerous to health when used in the dosage prescribed on the label. Accordingly, the court decreed that the articles of drugs should be condemned according to the provisions of the Food, Drug, and Cosmetic Act—*United States v 11¼ Dozen Packages, 40 F Supp 208 (N Y, 1911)*

Medical Practice Acts Revocation of License for Performance of Abortion—The California board of medical examiners, after appropriate notice and hearing, revoked the license of Tobin, to practice medicine on a charge that he had been guilty of unprofessional conduct in that he performed a criminal abortion on a married pregnant woman. The physician sought by a writ of mandate to compel the board to annul its order of revocation. The trial court denied the writ and the physician appealed to the district court of appeal, second district division 2, California.

The physician claimed that the evidence received by the board in its hearing was insufficient to justify its action in revoking his license. There was, the physician contended, no evidence that the married woman was pregnant or that the physician had performed an abortion on her or had attempted to do so. But said the appellate court, it appears from the transcript of the proceedings before the board that the woman in question testified that before going to the physician's office she had experienced nausea and dizziness for about six weeks and that she had missed one menstrual period, that she knew she was pregnant and went to the physician's office for the purpose of having an abortion performed, that she visited the office one day and had a discussion with a nurse employed by the physician, that she returned to the office two days later at which time the physician operated on her by using instruments in her uterus, that her husband paid \$60 to the nurse in the physician's office and that this nurse was in the room while the operation was being performed. The husband testified that the physician told him in a conversation subsequent to the operation that it couldn't have been a very long pregnancy. Agents of the board of medical examiners testified that the physician told them in so many words that he had performed an abortion on the woman in question. There was also testimony at the hearing that after the operation the physician had paid \$130 to the woman's husband, which sum, the physician claimed during the course of the hearing was a "loan" to the husband. We are satisfied, said the court, that the evidence referred to above is sufficient to sustain the order of the board of medical examiners in revoking the physician's license.

After the operation was performed by the physician the woman was taken to the Los Angeles County General Hospital for treatment. During the course of the hearing before the board certain records of the hospital concerning the case were admitted in evidence and the physician contended that the action of the board in admitting such records was erroneous. But said the appellate court, the resident surgeon of that hospital testified that he examined the woman on April 19, the day she was admitted to the hospital, and that she remained in the hospital until May 13, that the woman told him that an abortion had been performed on her about two weeks previously, that she had had slight bleeding for some two days following the abortion and then was apparently well, that one week later she had chills and fever, that his diagnosis was postabortal abscess, that he had made this diagnosis from statements made by the woman but that so far as his examination disclosed he could not tell whether her trouble

had resulted from an abortion or from gonorrhea. The hospital records objected to contained notations by physicians other than the resident surgeon in which the woman's trouble was characterized as "postabortal." Whether the hospital records, and the appellate court, were authenticated in such manner as to be admissible in accordance with the strict rules of procedure to be followed in criminal cases need not be decided for an administrative board passing on the issue of the revocation of a license to practice medicine is not limited by the strict rules applicable to trials of criminal cases. Moreover, we are satisfied that the physician could not have been prejudiced by the introduction of the hospital records. The resident surgeon by his testimony fully informed the members of the board of medical examiners concerning the woman's condition while she was at the hospital, and the basis for the use in the records of the words 'postabortal' was fully explained to them.

The appellate court accordingly affirmed the action of the board in revoking the physician's license to practice.—*Tobinsky*

Board of Medical Examiners of State of California 121 P (2d) 861 (Calif., 1942)

Malpractice Injury from Circumcision, Res Ipsa Loquitur—The plaintiff, an infant son, was taken by his father to the office of the defendant physician for the purpose of undergoing a circumcision. The defendant, with his wife's assistance, performed the operation, using a circumcision clamp. The father was asked to return the plaintiff for examination within a few days but though the mother talked to the defendant's wife about bleeding the child was never taken back as requested. Two weeks later the plaintiff was taken to another physician who examined him and later performed another circumcision also using a circumcision clamp. The second physician later stated that in performing the second operation he had to cut through scar tissue and that this necessitated dilation of the skin of the organ after the operation. The jury found for the plaintiff and from an order denying an alternative motion for judgment notwithstanding the verdict or new trial, the defendant appealed to the Supreme Court of Minnesota.

The only question raised on appeal that had to be considered was whether or not the defendant was entitled to a judgment notwithstanding the verdict. The duty or legal liability of a physician or surgeon in treating his patients, said the court is well settled. Though he does not insure a good result he must exercise the skill and care that an ordinary member of his school would exercise in his locality. Thus continued the court, two obligations are imposed on a physician or surgeon though the dividing line between those obligations is sometimes obscure: (1) To use ordinary skill in diagnosis and method of treatment; (2) to use reasonable care in the manner in which that treatment is applied or, as in this case the operation performed. The plaintiff alleged lack of both skill and reasonable care. In the first place, said the court, in regard to skill, plaintiff introduced no evidence of the approved or standard method of performing a circumcision in that community, nor did he offer any evidence tending to show that the defendant's methods were unskillful. His only expert witness refused to characterize the defendant's surgery as either unskillful or negligent. The defendant testified that he performed the operation according to methods ordinarily used and approved in his locality, and his testimony was not contradicted or impeached. The plaintiff, therefore, failed to prove that the defendant did not use the required skill in operating on the boy. Secondly, in regard to reasonable care the court said that the only testimony describing the manner in which the operation was performed was produced by the defendant. This testimony showed no lack of reasonable care and there was no other proof of negligence.

The plaintiff argued that he had proved a fact situation entitling him to the benefit of the doctrine of *res ipsa loquitur*, which in a proper case has the effect, in the absence of evidence destroying the inference favorable to plaintiff of saving him from a directed verdict for defendant. The application of the doctrine permits the trier of fact, in the absence of evidence of specific acts of negligence, to reason from the result back to

the cause—to infer fault on the part of the person having control of some instrumentality from the failure of its operation to terminate in a safe or proper result when ordinarily a safe and proper result follows the exercise of care. The court held, however, that no inference of lack of skill or care can be drawn from a failure on the part of a physician or surgeon by treatment or operation to effect a cure, since such failure to cure occurs under the most skillful and careful treatment. Accordingly, the court concluded that the order of the trial court denying the defendant's motion for judgment notwithstanding the verdict was improper and the order was reversed with directions to enter judgment in favor of the defendant.—*Johnson v Colp 300 N W 791 (Minn., 1941)*

Marriage and Divorce Insistence of Husband on Use of Contraceptive as Desertion Warranting Divorce—The unjustified refusal of sexual intercourse, said an advisory master to the court of chancery of New Jersey, persisted in for two years or more by one party to a marriage is a ground for divorce for the cause of desertion. This rule rests on the principle that refusal of sexual intercourse prevents the procreation of children and thereby defeats the controlling purpose of marriage which is to enable the sexes to gratify lawfully the natural desire for procreation which has been implanted in them that the race may be preserved. Such purpose is likewise defeated when one of the parties solely for his or her own personal selfish convenience insists on contraception to prevent the female from becoming impregnated. Under such circumstances, if the conduct is persisted in for two years or more the aggrieved spouse is entitled to a divorce on the ground of desertion. In this case a decree of divorce on the ground of desertion was advised on the complaint of a wife that her husband refused for two or more years over her protests to have natural 'uncontracepted' intercourse with her. It is unthinkable said the advisory master, that a wife in full health her maternal instinct clamoring for the realization of her desire to become a mother may, because of the selfishness of her husband, be condemned during her marriage to him to a life of frustration of that maternal instinct and desire with all of the deleterious physical, emotional and mental effects that follow such frustration.—*Kreyling v Kreyling 23 A (2d) 800 (N J., 1942)*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Peptic Ulcer and Irritable Colon in the Army—Chamberlin states that, of the 3492 army men admitted to the Lawson General Hospital between August 1941 and May 1942 1755 were medical patients and 9 per cent of the total or 18 per cent (316 men) of the medical patients were admitted to the gastrointestinal section. Of the 316 98 had peptic ulcer (3 gastric and 95 duodenal) and 128 functional digestive disturbances. Most of them were discharged on certificates of physical disability. Of the 18 officers affected only 2 were sent to limited duty, the other 16 were either retired, in the case of the regular army or sent to inactive duty in the case of the reserves. Without the assurance of a permanent position or station it is not safe for an ulcer patient to be on duty. Of the 128 with functional disturbance 113 were enlisted men and 15 officers. The disorder was principally an irritable colon. The problem of the disposition of these individuals arose. Of the 113 76 were discharged on certificate of physical disability with the diagnosis of "intestinal indigestion" and 37 were returned to duty, after two weeks to three months of treatment they became symptom free and were able to tolerate the general mess. These patients, it was felt would be able to carry on without further hospitalization for their digestive symptoms. Of the 15 officers, 4 with hyperchlorhydria or hypertrophic gastritis were sent to duty and of the 11 with irritable colon acute diarrhea developed in 4 on the slightest deviation from diet. They were placed on an inactive status and 7 were returned to duty. Only 1 of this group was readmitted with a recurrence. The psychic factors played a more prominent part among these officers than in any other group. The remaining men received on the section had the ordinary conditions seen in civilian practice. Their disposition presented no unusual problems.

B Vitamin Deficiencies and the Gastrointestinal Tract—Martin and his co-workers studied the effect of the different components of the vitamin B complex on the secretion and motility of the gastrointestinal tract in each of six sets of 5 dogs 6 to 8 weeks old. In each of the sets other than the set which received both inositol and pantothenic acid there were common features on roentgen study suggesting that the two factors inositol and pantothenic acid are both associated with the maintenance of a normal gastrointestinal function. Other factors, such as pyridoxine, may influence the general picture. The two factors appear to be interdependent. The following features characterize the picture if either is absent from the diet: increased gastric emptying time with pyloro-

spasm, decided segmentation of the small and the large intestine, hypertonicity with hypomotility, alternation of the ribbon-like segments with dilated loops and frequent formation of gas and fluid levels.

Rheumatic Heart Disease Complicating Pregnancy—From 1931 to 1940 there were sixty one maternal deaths due to rheumatic heart disease which constitutes the principal type of heart disease in women of childbearing age. During this time there has been a steady decline from seven and nine tenths deaths per thousand live births in 1931 to three and one tenth in 1940. The study shows that every gravid woman with organic heart disease represents a potential fatality from her cardiac lesion and therefore requires special care during her pregnancy. The fatalities were principally due to congestive heart failure following delivery at or near term. Hoffman and Jeffers state that if there is to be a significant decrease in the maternal death rate among cardiac patients permitted to attempt childbearing it must come through the prevention of congestive failure, which prior to delivery is largely a problem of antepartum care and after delivery is directly related to the cardiac status at the time of delivery. Almost 50 per cent of the postpartal deaths occurred among women who were decompensated at the time of labor or when termination of the pregnancy was undertaken. The burden of labor on congestive failure deserves further study. The emptying of the uterus is the primary factor precipitating death. The emptying and subsequent contraction of the uterus forces blood from the large uterine vessels and sinuses into the general circulation which seemingly cannot be properly distributed by a damaged heart. Since the cardiac burden imposed by labor does not appear to be critical it would seem that vaginal delivery is preferable for most cardiac patients without obstetric complications. The mortality rate due to rheumatic heart disease complicating pregnancy can possibly be lowered by having the patients at delivery in the best possible condition, by immediate therapy of intercurrent infection by hospitalization prior to expected delivery, by partial digitalization prior to delivery and by deferment of delivery, if possible, while the

patient is decompensated. Postpartum signs of decompensation must be anticipated and proper treatment instituted. Fluids intravenously should be avoided particularly within the first twenty-four postpartum hours, since they may precipitate congestive failure.

Sulfadiazine in Pneumonia—Eusworth and his colleagues used sulfadiazine for the treatment of 239 patients with pneumonia. Twenty-six patients died, giving a fatality rate of 10.9 per cent. Eight of the deaths occurred in less than twenty-four hours after treatment was instituted. The most striking results were obtained in 42 patients with type II pneumonia, of whom only 3 died, 2 less than twenty-four hours after treatment was started. Thirteen of the 42 had bacteremia and all but 2 recovered. Division of the cases according to the time sulfadiazine therapy was commenced shows that of 108 patients treated within the first three days of onset only 7 died (6.5 per cent, 1 twenty-four hour death is excluded) and that of those treated on the fourth day or later 11 died (8.9 per cent, 7 twenty-four hour deaths are excluded). The effectiveness of sulfadiazine appears to be the same as that of sulfapyridine and sulfathiazole.

Effect of Amphetamine Sulfate in Gelatin—A gelatin solution of amphetamine sulfate for parenteral introduction was used by Myerson and his co-workers to prolong the effects of the drug by delaying its absorption. Its effects, as compared to an aqueous solution, revealed the following: 1. The increase in blood pressure and the corresponding decrease in pulse rate produced by amphetamine was not delayed or prolonged when the drug was dissolved in gelatin. 2. There was a definite prolonged decrease in gastrointestinal tone and peristalsis when the drug was mixed with gelatin. 3. The delay in the absorption of alcohol which follows the administration of amphetamine sulfate was also definitely more pronounced.

Treatment of Underweight with Insulin—In treating 30 underweight patients Greco and his associates used insulin with most satisfactory results. They injected insulin once a day beginning with 8 units and increasing according to the patient's appetite on the previous day, a dose of 30 units was never exceeded. The drug was administered about forty-five minutes before the noon meal but the patients were advised to eat when they began to feel hungry. When a sufficient gain in weight was attained the administration of insulin was gradually discontinued. In this way the stimulus to the pancreas was gradually restored so that if it was spared during treatment it regained its function progressively. The administration of insulin only once a day and its gradual discontinuance protects the endocrine function of the pancreas. Glycosuria was not encountered. The unanimous statement of the patients was that they ate "as never before in their life." That the effect of the pancreatic hormone was not psychic was demonstrated by injecting sterilized isotonic solution of sodium chloride instead of insulin; the result was that all the patients thus treated lost their appetite. When they were returned to insulin their appetite again improved.

Tetanus Following Eye Injury—A case of tetanus following injury to the eye is reported by Wetzel who stresses that although prophylactic antitoxin was administered at the outset the classic syndrome of cephalic tetanus supervened.

In the literature 30 cases of head tetanus have been reported. In most instances the causal factor was an object immediately associated with horses or with earth which could easily have been contaminated with the excrement of horses. Only 6 of the 30 patients survived. Tetanus antitoxin was administered to all who recovered, suggesting that it may be advisable to administer it as a routine in injury to the eye. The author's case supports this recommendation. A farmer had a ricocheting nail strike him in the left eye. That same day he was given a prophylactic injection of 1,500 units of antitoxin. The prolapsed iris was excised under local anesthesia, the wound repaired and a pressure bandage applied. The patient was discharged on the eighth day. He returned four days later with evidence of tetanus. Intensive antitoxin therapy was instituted. On the seventh day of his second hospitalization a stormy convalescence began and not until twenty-six days after the original injury was it deemed wise to remove the left eye. Convalescence from this operation was uneventful.

Low Back and Sacral Pain—Brav and his associates compared roentgenologic appearances in 70 cases of low back and sciatic pain with those in 35 control subjects with no symptoms. 1. Normal roentgenograms, vertebral epiphysitis and osteochondritis narrowing of the intervertebral disks (except the fifth lumbar) and vertical herniation of the nucleus pulposus were encountered in similar proportions in the two groups. 2. Lumbar anomalies were present in 48.5 per cent of both groups. 3. Lumbarization of the first sacral segment and sacralization of the fifth lumbar vertebra were noticed almost entirely in females. 4. Hypertrophic arthritis of the spine was twice as frequent among those with backaches. 5. Scoliosis

and increased lumbar lordosis were twice as frequent and flattening of the lumbar spine six times as often in the backache cases. 6 There was no direct relationship between the clinical diagnosis and the areas on the roentgenograms showing the most definite abnormality. 7 Lumbar abnormalities were four times as frequent and lumbosacral abnormalities four and a half times as frequent in the group with backaches. 8 Sacroiliac changes were present in the roentgenograms of 6 of the backache cases and in none of the controls. 9 The oblique films of the articular facets of the two series revealed no information of diagnostic importance. 10 There were 4 patients with posterior displacement of the fifth lumbar vertebra in the backache group and none among the controls. 11 Narrow posterior disk measurement was observed in 20.6 per cent of the backache cases and in 5.7 per cent of the controls. This was much more frequent in patients more than 30. There was no relationship between narrow posterior disk measurement and the incidence of radiating leg pain. 12 Narrow anterior disk measurement was about equal in the two groups and was probably of little significance unless the posterior disk measurement was also narrowed. 13 The disk angle and the lumbosacral angle measurements showed no significant differences in the two groups. 14 Narrow posterior fifth lumbar disk measurement and posterior displacement of the fifth lumbar vertebra as recognized on the roentgenogram appeared to be definite etiologic factors in the production of low back and sciatic pain.

Treatment of Cancer of Skin of Nose—Robinson and Harris state that in their 146 cases of cancer of the skin of the nose the results were satisfactory in all but 12 advanced cases following single massive or divided doses of roentgen rays and/or radium with or without surgery or electrodesiccation.

Treatment of Epithelioma of Skin of Ear—The results of the roentgen treatment of 130 cases of epithelioma of the skin of the ear are reported by Driver and Cole. The cases represent an incidence of 5.5 per cent of a total of 2,364 cases of cutaneous epithelioma treated during twenty-five years. The age incidence average 64.3 years, corresponds to that of cutaneous epithelioma in general. There were 96 men and 34 women. The treatment cannot be standardized. Many cases that formerly would have been considered hopeless are now successfully treated with the modern technique of employing radium and roentgen rays. Divided doses of roentgen rays were used for 27, interstitial gamma irradiation with low intensity, heavily filtered radium needles in 10, gamma irradiation in cases in which cartilage was involved, electrodesiccation and curettage or electrocautery and curettage alone or combined with surface irradiation in 66 patients, the unfiltered glass radon bulb for keratosis and early superficial epitheliomas, for primary involvement of the external auditory canal radical surgery or thorough destruction with the electrocautery or electrocoagulation followed in some instances by radiation therapy and for melanoepithelioma thorough destruction or radical excision. There were 44 patients who had suffered recurrences following previous treatment and 10 who had recurrences following treatment given by the authors. Recurrence usually results from insufficient treatment and often seriously complicates further therapy because of metastasis or cancer cells in scar tissue. Seven patients had metastasis, 1 of them with involvement of the postauricular node has remained well for more than eight years after receiving 840 millicurie hours of interstitial irradiation with low intensity radium needles, in 2 direct extension from infiltrating overlying cancer involved the preauricular node and treatment by interstitial radium needles effected a cure in both and in 5 the cervical nodes were involved and all have died as a result of cancer. Of the 130 cases 107 have been followed for more than one year. 37 have remained cured for more than five years, 24 for three to five years and 46 for one to three years. Of the 107, 9 are known to have died of metastasis or of uncontrolled spread of the growth. There were also 4 who died of cancer in less than one year, leaving 94 with possible cures of one to five or more years. The results compare favorably with those obtainable with epithelioma of other areas of the skin.

Primary Lesions of Pemphigus Vulgaris—In the 3 cases of pemphigus vulgaris that Oppenheim and Cohen report the condition began with a localized lesion that occurred prior to the generalized eruption and was resistant to therapy. In case 1 it began three months before with a burn on the flexor surface of the right elbow joint where blisters and crusts formed in spite of treatment. The generalized rash of bullae and vesicles developed into malignant pemphigus vegetans. In case 2 three months prior to the generalized eruption several blisters appeared on the center of the scalp and did not heal. In case 3 the condition began with a crusting eruption of the scalp followed in two months by a generalized bullous eruption on the body. The condition in cases 2 and 3 was of the benign type, as was shown by the appearance of bullae on otherwise normal skin. The lesions in case 2 healed with the formation of many sebaceous and horn cysts, as do those of epidermolysis bullosa hereditaria. In case 3 the Nikolsky sign was present and the reaction to the iodine test was negative. With these findings a diagnosis of dermatitis herpetiformis of Duhring is not tenable.

Roentgen Irradiation in Acne Vulgaris—Kline and Gahan treated one side of the face of 50 random patients who had acne vulgaris with ten exposures to one fourth of an erythema dose (75 roentgens) of unfiltered roentgen rays at intervals of one week. Thirteen patients discontinued attendance, 1 had an erythema and therapy was stopped, and another had rosacea and showed no improvement. Twenty patients showed as much improvement on the treated as on the untreated side, 9 showed improvement only on the treated side, and 6 showed no improvement on either side. The scarring produced by the acne was no greater on the treated than on the untreated side. This confirms the opinion that safe therapeutic doses of roentgen rays are no more likely to increase scarring than any other method of treatment. The good results cannot be attributed solely to a functional atrophy of the sebaceous glands; the rays must have another still undetermined effect.

Bullous Dermatitis Herpetiformis—During five years Goodman encountered 15 patients with a bullous type of dermatitis herpetiformis. Only 5 were less than 50. Although the eruption may be extensive there is a greater tendency toward localization than in typical dermatitis herpetiformis and also toward annular grouping of the bullae. The bullous elements coalesce to form peculiar inflammatory plaques at the periphery and where fresh bullae continue to form. The condition usually responds well to arsenical therapy, in combination with other general measures an apparent cure was affected in at least 3 cases. Vitamin D seems to have some value in controlling

the disease. Because of its special features and the tendency for lesions to develop in the flexures and intertriginous areas, the disease apparently has often been mistaken for pemphigus. However, pemphigus occurs most frequently in persons between 20 and 50 years. It is suggested by the author that all cases especially occurring around the age of 50, previously recorded as instances of controlled or cured pemphigus should be reviewed in the light of his present observations.

Complication of Paravertebral Injection of Alcohol—

A third disastrous complication following the accidental injection of alcohol either into the spinal cord or intrathecally instead of paravertebrally for the relief of angina pectoris is reported by Hirschboeck and Gillespie whose patient thirteen months after the injection had all component motions in the left leg but still had difficulty in stabilizing himself on standing and walking. Dissociation of sensation was present on the right side up to the crest of the ilium. To prevent complications suction on the syringe to make certain that the needle is not in the spinal canal and observation of the sensory and motor function of the lower extremities after injection should always be carried out.

Active Sensitization with Trichina Antigen—Baron and Brunner tried to determine whether the cutaneous test doses of Trichina antigen used as a diagnostic aid in detecting Trichinella infection can sensitize patients to this antigen. If this was possible it seemed desirable to study the immunologic mechanism involved and the relationship of the sensitiveness of Trichinella spiralis and Ascaris lumbricoides. The study was made on three groups of 6 atopic subjects who were attending the allergy clinic for the treatment of various allergic illnesses. The subjects were first tested intracutaneously with 0.01 cc of Trichina antigen and only those giving negative reactions were used. Injections of 0.1 cc were then given at intervals of one to two weeks for four to twenty weeks. Cutaneous reactions were read within fifteen minutes after testing. With the development of hypersensitivity a positive reaction ensued. It consisted of an erythema and an itch which appeared about five minutes after the injection. Wheal formation then followed. In 10 of the 18 subjects, sensitivity as indicated by definite wheal and erythema formation was induced at least 1 plus intensity occurred with the third sensitizing dose in 2 with the fourth in 1, with the fifth in 3 with the sixth in 1 with the seventh in 1, with the eighth in 1 and with the ninth in 1, in 2 doubtful reactions never more than a \pm in intensity were obtained. The cutaneous reaction in sensitivity to Trichinella spiralis was mediated by the atopic reaction and was transferable to the normal skin. A

common antigen exists in *Ascaris* and *Trichina* antigens. It is probably stronger in the *ascaris* than in the *Trichina* extract, even though the *Trichina* antigen transfers better on *Trichina* serums. It should be remembered that the diagnostic value of the *Trichina* tests diminishes on repetition.

Vegetable Milk Substitute—As a result of investigations by the Ewa Health Project and the United States Department of Agriculture a dehydrated taro meal has been made available which retains in a large measure the natural attributes of the freshly cooked taro root, one of the oldest economically important foods known to man. Feingold offers the following taro recipe as an addition to the small group of vegetable milk substitutes already available for children sensitive to milk: 20 Gm (5½ teaspoons) of pyo meal (taro), 4 Gm of clear gelatin, 10.8 Gm of vegetable oil, 7.5 Gm of corn syrup, 2 Gm of calcium gluconate, 2.4 Gm of sodium chloride and water to make 240 cc. The ingredients are cooked over the direct flame for three minutes. After cooking the original volume is restored by adding water. At the current market prices a quart (1000 cc) of the formula costs 11 to 13 cents.

Treatment of Psoriasis with Sarsaparilla Compound—During the last two years Thurmon administered sarsasaponin tablets to 75 patients with psoriasis and as a control employed a dietary regimen and local therapy for 17 others. The

sarsasaponin tablets must be taken regularly for three to seven months. The usual adult dose is one tablet twice a day, preferably taken with a warm liquid at a time when the stomach is most likely to be empty. A diet low in fat will prove beneficial to many patients. The tablets used were about one fifth as concentrated as those commercially available at present. The clearance was 100 per cent in 14 patients, 75 per cent in 16, 50 per cent in 17 and 25 per cent in 12, there was no improvement in 14 and there was an exacerbation in 2. Of the control patients 1, 1, 2, 3, 7 and 3 patients had corresponding results. The author concludes that sarsasaponin is worthy of clinical trial in any case of psoriasis. There were no toxic systemic effects from its use. The appetite of many patients increased, they gained weight and seemed less nervous, slept better and experienced less itching. Three women took the sarsasaponin during pregnancy without ill effect and their psoriasis improved. The drug appeared to have a greater value in clearing the chronic, large plaque type of lesion than it had in controlling the recurrent evanescent and exanthematous punctate, nummular and guttate lesions. The newly recurrent eruption was milder, but it did appear despite the medication. A history of familial incidence was obtained from 15 patients. In contrast 53 were the parents of 121 children none of whom had psoriasis. This indicates that psoriasis is not a deterrent to marriage and the begetting of progeny.

Calcium Therapy in Bacillary Dysentery—Block and Tarnowski compared the effect of calcium administered parenterally and orally to children and infants with bacillary dysentery with that of belladonna, bismuth subcarbonate, kaolin and insulin. Twenty-nine were males and 20 females from 10 months to 55 years. 32 between 2 and 8 years received calcium, and in the control group 19 were males and 13 females from 9 months to 60 years, 28 were from 9 months to 9 years of age. The morbidity of patients on calcium treatment ranged from five to one hundred and fifty days for the male and four to one hundred and fifty days for the female, the respective averages were thirty-nine and one-tenth and forty-one and one-tenth days, but 58.8 per cent of all patients on calcium were discharged within thirty days as against only 35.3 per cent of the control patients. The results of the study justify the conclusion that calcium is effective even when not supplemented by other drugs, vitamins or hormones. However, its action can be greatly enhanced by vitamin D and the condition of the bowel relieved by the addition of kaolin. In the control series at the beginning of the study the proctoscopic examination of 11 was negative, of 9 impacted, of 2 ulcerated and of the remainder hyperemic. With the exception of 2 patients who died none were acutely ill. At the expiration of the investigation the study of 25 was negative but only 21 were discharged, ulceration was still present in 1 and 10 were continued to be held in isolation. In contrast, in the calcium group the study of 14 was negative and showed impaction in

4 ulceration in 5 and hyperemia of various degrees in the rest. At the end of observation, the study was negative in 34 and they were discharged, 10 were returned to isolation and 1 died. Calcium resulted in the recovery of every patient with an ulcer.

Alcoholism—Medical Problem M Moore Denver—p 564

Anal Infection—Nesselrod explains anal infection on the basis of a chain of events which occur in the pathogenesis of anorectal inflammatory disease. Infectious intestinal material especially when it is soft or liquid, can easily gain entrance into one or more anal crypts. The tiny, vestigial anal ducts which lead from the bottom of the crypt to rudimentary glandular follicles afford excellent ports of entry. The lymphatics probably play an important role in anal infection. An underlying etiologic factor of which the profession does not seem to be aware is that anal infection provides the first step in the development of the phlebitis which underlies hemorrhoidal disease. It takes part in the development of anal fissure, abscess, fistula and related conditions, that is these common disorders constitute various manifestations of anal infection. Any therapeutic procedure which ignores anal infection is likely to fail as far as the cure of anorectal inflammatory disease is concerned.

Acute Intussusception of Childhood—In 16 instances of acute intussusception of no demonstrable cause in children Aveni observed that mesenteric lymphadenitis was present as an associated lesion in 7. It is possible that the lymphadenitis is of more frequent occurrence as the 16 patients were operated on by six resident surgeons who were not looking for the disease and mentioned it only as a passing observation. The mesenteric lymphadenitis may assume an important etiologic role in acute intussusception, especially as almost all the acute intussusceptions of childhood are ileocecal, a fact which again lends credence to the importance of lymphoid hyperplasia as its cause.

Effect of X-Rays on Infections and Inflammations—According to Weed and his collaborators, their study of the effect of roentgen rays on *Clostridium welchii* in vitro and in such infection in guinea pigs has not demonstrated any real beneficial effect with doses even beyond those permitted for human therapy.

Exclusive Use of Soap and Water in Traumatic Wounds—Kerrigan reports the results of proper cleansing exclusively with soap and water, of 12,044 open wounds treated over five years resulting from 21,862 industrial injuries. Hospitalization was necessary for only 18 cases in which the primary care consisted of white soap and water cleansing and excision of only devitalized tissue. Of 9,195 compound wounds involving the wrist and hand only 10 of the patients required hospitalization. As these injuries were so uniformly contaminated and so difficult to cleanse and because in no instance in which primary soap and water cleansing was given was it necessary to hospitalize an individual for infection the authors feel that this is the severest test for the efficacy of the method. The method is also successful in the hands of nurses who care for many of the minor compound wounds. Among 101 cases of compound fracture 4 infections occurred. There was no osteomyelitis or delayed union.

Postoperative Thrombosis and Embolism—Priestley and Barker reviewed the records of the patients undergoing various surgical procedures during thirteen years and discovered 1,665 cases of pulmonary embolism and thrombophlebitis or an incidence of 0.95 per cent. Actually the incidence is probably higher, as some instances of mild thrombophlebitis or small pulmonary emboli were undoubtedly not recognized. There were 343 fatalities. Certain factors appear to be significant in the development of these conditions. The site of operation (pelvic) apparently bears some relationship. There is a predisposition in the presence of cancer. Splenectomy was followed by the highest incidence of embolism. Infection has some relation, as thrombosis and embolism occur with much greater frequency after an operation for a ruptured appendix than after removal of an unruptured appendix. Obesity and thrombophlebitis are higher in women than in men, but pulmonary embolism, both fatal and nonfatal, is higher in men than in women. Why this is so cannot be explained on the basis of the difference in surgical procedures performed on the two sexes. Thrombophlebitis occurs most often between

the ninth and fourteenth postoperative days, and pulmonary embolism, both fatal and nonfatal, between the seventh and fourteenth days. It seems certain that a relationship exists between venous thrombosis or thrombophlebitis and embolism and vice versa as the conditions were associated in one fourth of the cases. There appear to be three main etiologic possibilities for postoperative venous thrombosis: decrease in the rate of venous blood flow with resultant stasis; trauma or some other type of change in the wall of the vein and some abnormality in the blood itself. The serious difficulty in the preventive treatment of thrombosis and embolism is the inability to determine preoperatively in which patient if he is not treated thrombosis or embolism may develop. Heparin has been most effective in increasing the rate of venous flow, but unfortunately in its present form it is not suitable for routine postoperative use. As heparin is not to be administered to every surgical patient it would appear reasonable to employ it for any person who, because of previous phlebotic or embolic phenomena or other reasons, is expected to experience further difficulties in this regard. Otherwise the group of patients in whom embolism is most likely to occur is that group who have already experienced one episode of nonfatal embolism. Clinical experience with heparin in patients who have had nonfatal pulmonary embolism has been most gratifying. It was administered to 63 such patients and only 2 of them died of another episode of embolism. The authors' experience with heparin in thrombophlebitis has been limited, but it is their impression that heparin will prevent further growth of a thrombus and in this manner prevent aggravation of the condition. Also it prevents other thrombi from developing during its administration. In addition to the use of heparin and the conventional treatment by immobilization, elevation and heat the other suggestions made during recent years for the treatment of thrombophlebitis have been paravertebral injection and venous ligation.

Biologic Properties of Highly Purified Penicillin—According to Florey and Jennings the purest preparation of penicillin so far available completely inhibits the growth of *Staphylococcus aureus* at a dilution of between 1 in 24 and 1 in 30 million. An intravenous injection of 20 mg. of the sodium salt of a somewhat less pure preparation was without apparent effect on a mouse, and human leukocytes survived for an hour in a 1 per cent solution. Even if citrim and penicillic acid should prove to be useful therapeutic agents too much emphasis should not be laid on their easy availability as penicillin is five hundred times as active against many organisms and it is certainly nontoxic.

Melorheostosis—Franklin and Matheson report a case of melorheostosis of extensive distribution in a woman of 41 with symptoms for at least fifteen years. For the last ten to fifteen years she has had a recurrent ulcer of the dorsum of the right foot, for which condition she was hospitalized. Changes typical of melorheostosis are present in many bones of the right half of the skeleton while with the exception of the fifth lumbar vertebra all the bones of the left half appear normal. The principal change is an extensive hyperostosis along the medial aspect of the skeleton of the right upper and lower limbs and in some of the bones of the skull, ribs and spine. In the long bones this hyperostosis gives rise to much thickening and distortion of the shaft, the surface of which is either wavy or nodular. There is a varying degree of encroachment on the medullary cavity. In some of the bones long, narrow dense streaks are seen. In the extremities of the bones small patches of hyperostosis are seen. The articular surfaces are unaffected but in the lumbar spine there are some periarthral bony outgrowths arising from the right articular processes. There is no apparent restriction of movement. In the skull spine carpus and tarsus the distribution of hyperostosis is fairly even throughout, while in the tarsal bones there is also coarsening of the trabeculation. Apart from the bone changes there are some extremely dense nodular deposits in the soft tissue to the inner side of the lower end of the right femur, behind the right ankle joint, below the right hip joint and near the superior angle of the right scapula. The two points of special interest are the wide spread and unilateral distribution of the condition and the fact that an upper and lower limb are involved. The roentgen appearance of melorheostosis is as though an excessive amount of bone had been poured down one aspect of the bones. The various hypotheses offered to explain the etiology of the condition do not apply when the character and distribution of the lesions in the author's case are considered. The etiology of melorheostosis remains a mystery.

Mental Symptoms in Bromide Intoxication—Kitching reports 9 cases of bromide intoxication. Mental symptoms were prominent in all bromide intoxication either was the main illness or arose during the treatment of some other condition. One patient died the rest recovered with sodium chloride treatment although 2 were seriously threatened. The diagnosis depends on the mental and physical signs and the history; it is confirmed by the blood bromide estimation and the response to treatment with chloride. Of the mental signs confusion, clouding of consciousness is the most important. The normal blood bromide is 0 to 25 mg per hundred centimeters. The level at which toxic symptoms begin varies with idiosyncrasy, tolerance due to prolonged intake, age, renal or hepatic disease or restricted diet. Levels of less than 100 mg can be ignored, those of 100 to 200 mg may produce symptoms in elderly patients or patients with cardiovascular or renal disease and those of more than 200 mg produce symptoms in most patients. The therapeutic test is specific: if sodium chloride causes rapid amelioration of symptoms, the diagnosis of bromide intoxication becomes a certainty. The usual dose is 2 to 4 Gm four times a day.

Tetany in Blood Donors—The incidence of tetany following blood donation is reported by Frazer and Fowweather as being 1 in 1000. The signs, typical spasms of the hands and feet and positive Chvostek's sign, have been unmistakable. The number of donors affected is certainly small but the condition is important and has not been reported previously. The attack is not wholly dependent on the amount of blood withdrawn: in 1 donor it occurred after the removal of only 60 cc of blood in another after 400 cc and in 5 others after the full quantity had been drawn. Five of the attacks occurred in women. This is in agreement with the general experience that spontaneous hyperventilation tetany occurs mainly in females. The blood changes, consisting in a low inorganic phosphorus and high normal or raised calcium level, correspond to those found in other cases of spontaneous hyperventilation tetany. The principal factor concerned was believed to be overbreathing resulting from nervousness and apprehension. Another possible factor is the effect of epinephrine contained in the local anesthetic. The treatment recommended is to supply air enriched with carbon dioxide. If a supply is not available the patient should be caused to rebreathe his own expired air by placing a paper bag over his nose and mouth.

Syncope Reactions in Blood Donors—Williams tried to determine by investigation in 222 cases whether the fainting of blood donors was associated with any individual constitutional or circumstantial peculiarities. There was a definite correlation between certain individual and environmental factors and the incidence of these reactions. The avoidable factors were as follows: 1. Fainting was observed when supervision of the donors was not adequate. Rest immediately after the donation of blood was important. In one hospital where tea was served before the donors moved from their couches the rate was low. 2. While isolation is desirable for esthetic reasons it is not believed to affect the tendency, as donors are reassured by seeing others giving their blood. 'Epidemic fainting', however, is aggravated with no isolation and it is better for young donors attending in parties to be separated. 3. Donors known to be menstruating should not be accepted.

but it is not advisable to exclude such donors unless such information is given voluntarily. The unavoidable factors were the following: 1. The incidence of reactions was significantly higher among those of the 'asthenic' diathesis than among donors of more stocky appearance. This suggests that syncopal reactions may be associated with increased vagal tone. This hypothesis is further borne out by bradycardia and low blood pressure in such donors. 2. The higher incidence of fainting among donors less than 30 provides further evidence of increased vagal tone and syncope following transfusion.

Massive Overdosage of Acetylsalicylic Acid—The recovery of a patient after the taking of nearly 1000 grains (65 Gm) of acetylsalicylic acid is cited by Oakley and Donnell who state that the treatment of such acute poisoning is essentially that of acidosis and dehydration with vasomotor collapse. Acidosis is best treated by large doses of sodium bicarbonate and dextrose intravenously. The dextrose infusion must be controlled by frequent estimations of alkali reserve. For the dehydration with vasomotor collapse in this condition as in diabetic coma, large volumes of saline solution, plasma and adrenal cortex extract intravenously are indicated. The most prominent features of the poisoning were exophthalmos, profuse sweating, coma, delirium, fixed pupils, absent tendon jerks, extensor plantar response persistently raised pulse rate and low blood pressure and deep abdominal breathing.

Narcoanalysis in Treatment of War Neuroses—Wilde used pentothal sodium for the study of 50 neurotic soldiers encountered in thirteen months whose investigation was held up by resistance but who were physically fit to receive pentothal and could be persuaded to submit to the treatment. Thirty-five had a predisposition to neurosis prior to service, 31 had suffered actual war trauma. Of the 50 so treated 33 were rendered fit for duty and 17 were invalided. About half those invalided were fit to return to good posts in civil life, a fact which in some militated against the successful removal of the neurosis. The author has found sodium pentothal intravenously of assistance in hysteria in its various manifestations, anxiety states, the after effects of head and spine injuries, borderline psychosis, mental deficiency, doubtful epilepsy and in simulation and malingering.

- *Bee Stings. A J Jev Blake—p 74
 Is War Eugenic or Dysgenic? That Is: Does War Improve or Impair the Physical or Mental Qualities of Future Generations? H L Gordon—p 86

Bee Stings—Jev Blake states that little or nothing seems to be known about the nature of the venom of wasps, bumble bees and hornets. A sparrow stung by wasps dies of respiratory failure after a period of convulsions and somnolence. In human beings the reaction to bee and wasp stings varies with their idiosyncrasy. The hardened bee keeper may be stung by twenty bees and have nothing to show for it but a few small painless and transient pimples while another person may be stung but once and die in a minute or two if he chances to be hypersensitive to the venom. Hypersensitivity in human beings may take two forms, allergy and anaphylaxis. In the postmortem examination of persons killed by bee stings the following was found: (1) voluminous, overfilled, downy and emphysematous lungs possibly exuding frothy fluid, (2) overdistention of the right side of the heart and (3) splanchnic dilatation and hepatic engorgement. The poison or antigen of bee venom is believed to reside in its protein. East African bee keepers agree that the local bees are much more savage than those hived in England and some add that their individual stings are worse and more painful. The effects of bee stings in East Africa appear to be as severe as wasp stings in

England. In temperate climates swarming is confined to a few months in the spring and summer. But in Kenya wandering swarms of bees may be met on the road, on the farm or in the house at any time of the year. When they attack, they do so on a heroic scale. Death from one or more bee stings has been known to occur in Europeans, Asians and Africans in Kenya. The available mortality statistics are incomplete, but it may be supposed that half a dozen or more natives are killed by bees every year. Similar losses have also occurred among domestic animals and pets. Difficulties may arise in accounting for a death actually due to bee stings. Swarms of bees in the open or in the house should be given a wide berth by all except bee experts. Others should deal with them only after dusk, if something has to be done—spraying with flit or liquid petrolatum or the insufflation of pyrethrum powder. An attacked person is encouraged to stand still, not to run away, not to try and beat the bees off, that is to adopt the attitude of "nonviolent noncooperation." The local application of any form of alkali—weak ammonia or washing soda—is perhaps best for allaying the irritation of an ordinary bee sting. For wasp stings dilute acids such as vinegar, rather than alkalis, are recommended. In the rare severe case stimulants to keep the heart and respiration going, sedatives to relieve severe pain or muscular spasms, in fact symptomatic treatment is indicated. Good results have followed the use of a 25 per cent solution of nikethamide, solution of posterior pituitary and epinephrine administered hypodermically for severe shock, also black coffee and half a gram (0.03 Gm.) of ephedrine, and in France injections of camphor liniment have been recommended.

Macrocytic Anemia of Pregnancy A I Mudaliar and M K K Menon—p 284
Pruritus Vulvae Leukoplakia and Kraurosis Agnes Savill—p 310

Eclamptic Phenomenon and Placental Ischemia—Young presents evidence which shows that pregnancy toxemia (preeclampsia and eclampsia) is preceded and determined by an abortion factor which operates by interfering with the maternal circulation in the placenta. Two alternative mechanisms are recognized. 1 Stasis or complete arrest of the blood flow is restricted to certain regions, resulting in local placental degeneration. After complete arrest of the blood flow, if there is a sufficient interval of fetal survival with continuing circulation in the remaining placenta the ischemic area infarcts. 2 The vascular changes occur throughout the decidua and consist of dilatation and free blood extravasation. Retroplacental bleeding is an extreme expression of widespread vascular disturbance. In many instances both factors are operative. The toxemia develops subsequent to the placental degeneration. Its severity is determined by the extent of the placental involvement and the interval during which the fetus survives in utero. At least half of the placenta may be thus compromised before fetal death occurs. The relation of toxemia to the initial stages of the degenerative changes explains how after early fetal death or delivery the full extent of the placental involvement may not be visible macroscopically

or microscopically. This explains the high incidence and the severity of the toxemia in concealed accidental hemorrhage, and also that in many such cases there may be no evidence of toxemia. The latter are explained by immediate massive involvement and immediate fetal death. In concealed accidental hemorrhage (in which often an extensive muscular lesion is also present) an acute renal lesion with blood stained urine, oliguria or suppression and a rapidly rising blood urea may be superimposed on the typical preeclamptic or eclamptic phenomenon. A correlation has been found between the utero-placental lesion and toxemia only in severe cases, but none has been found between the placenta and the minor clinical manifestations of toxemia, the latter may arise from a lesion which eludes present methods of detection.

- *Bacillary Dysentery in Australian Hospital in the Middle East F R Hone E V Keogh and R Andrew—p 631
Relapsing Fever in Tobruk F I Cooper—p 635

Bacillary Dysentery in the Middle East—Hone and his colleagues describe the clinical features and management of 600 Australian, New Zealand and British soldiers admitted to an Australian general hospital in the Middle East. They restrict their article to some 300 cases of diarrhea arising among troops situated in the vicinity of the hospital and seen within the first few days of the outbreak. The striking feature of the cases was their mildness. Not only did no death occur, but no patient was considered "seriously ill." Only thirteen *Shigella* infections were encountered. The average stay of the patients in the hospital was about one month. This may seem excessive but the authors believed that premature discharge risked not only relapse but the establishment of a possible source of infection among healthy troops. It was their belief that a negative stool culture cannot be relied on in detecting potential "carriers," and they relied on the experience of Colonel Boyd and his colleagues who found that the healthy subject passing normal stools never excretes dysentery bacilli. For that reason a patient was not discharged until he was free from symptoms and his stools were of normal consistency and contained no mucus for several days. The introduction of sulfaguanidine may shorten hospitalization.

Relapsing Fever in Tobruk—Early in May 1941 spirochetes were found in the blood of 2 of the personnel of an Australian field ambulance corps living in a cave in the Tobruk fortress area. During the summer months May until August 68 patients suffering from relapsing fever passed through an Australian general hospital in Tobruk. Eight of these were evacuated from the fortress area and were later proved to have been suffering from relapsing fever although spirochetes were not found in their blood in the Tobruk hospital. Cooper followed the records of 63 of these men through hospitals and convalescent depots and he believed that the records were sufficiently complete to formulate a clinical picture of relapsing fever. Thirty-nine of the 63 soldiers affected had been living in caves or in old dugouts constructed by Italian troops. The shelters had not been inhabited by Italians or Libyans for three months prior to the first case of relapsing fever. Fever associated with spirochetes in the blood smear was the only feature common in all these patients. Some patients had in addition symptoms and signs suggesting involvement of the central nervous system, the reticuloendothelial tissues the renal tract or the lungs. Late involvement of the central nervous system with facial paralysis was relatively common. As there is no specific treatment, arsenic was given intravenously to most of the patients. All but 4 patients received inadequate amounts. It had no effect on the fever. Spirochetes were found in the blood of 17 arsenic treated patients. A pyrexial relapse occurred in 41 after arsenic was administered. However, its effect in this disease must be regarded as still not proved, as the dose used was not sufficient.

- Pathogenesis of Scarcity and Brachyuria C de Morsier—p 277
*Lingual Administration of Androgen K Miescher and P Gräse—p 279
Endocrine Preparations in Treatment of Emaciation Anita Saurer—p 281
Some Aspects of Problem of Blood Preservation R Eisler—p 291
Practical Filtration of Transfusion Blood R Bucher—p 297

Lingual Administration of Androgen—According to Miescher and Gräse the availability of testosterone propionate in tablet form is a great advance, but there seems to be no satisfactory relationship between the required dose when given by mouth or by the parenteral route. Biskind had proved that male as well as female hormones are largely destroyed by the liver. To circumvent passage to the liver, it was attempted to allow the preparation to be absorbed from the oral mucosa. The authors compared the effect of the lingual administration of testosterone and methyltestosterone on the seminal vesicles, prostate and other sexual organs of castrated rats with that of administration by stomach, using 342 animals. They found that alcoholic solutions of the two substances when given by the lingual route act from twenty to thirty times stronger than if they are given by the stomach. In case of lingual resorption the methyltestosterone is likewise superior to that of testosterone. It is about three times as effective.

Endocrine Preparations in Treatment of Emaciation—According to Saurer emaciation can be a manifestation of different disease entities. Latent infection or malignant tumor should be searched for and the possibility of an inadequate or one-sided diet should be considered. Inadequate utilization or excessive combustion resulting from metabolic disorders which in turn result from impaired neuroendocrine regulation, are other important factors. Since endocrine preparations have become available many of these disorders have become amenable to treatment. The author obtained some surprisingly favorable results with desoxycorticosterone acetate and with estrogens. She discusses 12 cases in the treatment of which ovarian and adrenal cortex extracts were used. In all but 1 of the cases of emaciation, in which infection and tumor could be excluded endocrine therapy improved the appetite and weight and the patients felt stronger. Three patients in whom emaciation was accompanied by secondary amenorrhea were treated with estradiol. This not only normalized the menstrual cycle but also improved the weight. Patients with Addisonoid symptoms were treated with desoxycorticosterone acetate and the result was a partial disappearance of these symptoms. In the majority of the examined cases of emaciation disorders of the carbohydrate metabolism existed. They differed in character, some were normalized by the medication and others were not. An effect on the fat and protein metabolisms could not be observed in the reviewed cases, but neither could it be definitely excluded. Simultaneously existing anemias were not influenced. Once a temporary hypertension resulted as a secondary effect of treatment with desoxycorticosterone acetate. This treatment also resulted several times in water retention, but the increase in weight cannot be entirely ascribed to this. The effect of the endocrine treatment is partly due to a specific substituting action but probably also partly to a nonspecific action. The results indicate that some cases of emaciation respond only to suitable endocrine therapy. It is assumed that corresponding metabolic disturbances in other diseases can be influenced in the same manner.

- *Circulatory Disorders Due to Avitaminosis B₁ Review of Literature J Moniz de Bettencourt—p 247
Uteroplacental Apoplexy Case J Fontes—p 260
Aspects of Antidiphtheric Immunization in a Territory of Lisbon J Cutileiro—p 284

Circulatory Disorders Due to Avitaminosis B₁—According to Moniz de Bettencourt, circulatory disorders due to avitaminosis B₁, namely dyspnea of effort and while lying down, palpitations, cardiac asthma, congestion of the lung, engorgement of veins, enlargement of the liver, edema and

ascites, hydrothorax and hydropericardium, are similar to those of benign cardiac insufficiency. Examination of the chest reveals dilatation of the heart and of the pulmonary artery and changes in the cardiac shadow as seen in mitral disease. Tachycardia, embryocardia, gallop rhythm and systolic or diastolic murmurs are heard on auscultation. As a rule there are no disturbances of the rhythm but there may be changes of the complexes of the electrocardiogram and sometimes inversion of the T wave. The acceleration of conduction with shortening of the PR segment of the electrocardiogram is rarely observed but it is a characteristic sign of avitaminosis B₁. In the course of avitaminosis B₁ the velocity of circulation and the cardiac output are increased and the utilization of oxygen by the peripheral nerves is diminished. The coexistence of venous stagnation, edema and increase of the velocity of circulation is of diagnostic value. Sudden collapse may develop. The causation of cardiovascular disorders by avitaminosis B₁ has been explained in the literature by several theories, such as disturbances of the metabolism of water due to avitaminosis B₁ with consequent cardiac edema and dysfunction of the myocardium, by local acidosis due to metabolic disturbances of lactic acid in the blood by local disturbances of the metabolism of glucosides and mainly by the interference with the sympathetic stimulation of the cardiovascular apparatus due to insufficient oxygenation of the nervous tissues. The therapy of circulatory disorders due to avitaminosis B₁, including sudden collapse, consists in administration of vitamin B₁ in large daily doses (from 20 to 50 mg a day). Administration of vitamin B₁ improves the capacity of the peripheral nervous tissues to use oxygen of the blood with resulting diminution of the dilatation of the arterioles and later disappearance of arteriolar dilatation, and diminution of the velocity of circulation. Diuresis increases, the subjective symptoms improve and later disappear, and the dilatation of the heart and electrocardiographic changes regress. The effect of vitamin B₁ therapy is rapid in the majority of cases (within three to five days). The good results confirm the diagnosis. In cases in which the effect is not rapid it is advisable to persist in the administration of the drug and to wait before excluding the diagnosis of avitaminosis B₁.

- *Elimination of Sulfonamide Compounds in Milk R Cibils Aguirre J R Calcarani D Aguilar Giraldes and H M Berisso—p 1
Idiopathic Anemia of the Newborn F J Menchaca—p 17

Elimination of Sulfonamide Compounds in Milk—Cibils Aguirre and his collaborators report studies on 49 puerperal women and on 34 newborn infants. They determined the excretion of sulfonamide compounds in milk, the concentration in the milk, its relation to the blood concentration and the proportion of the free and conjugated fractions. In all, 230 determinations were made. The author employed the technique of Bratton-Marshall for the blood and urine and the modification of Berisso for the milk. The customary therapeutic doses of sulfonamide preparations were given to the mothers. The newborn infants who were nursed by their mothers under these conditions never presented signs of toxicity or intolerance. This is in accord with the insufficient dose which they receive in the milk. The intake in the milk is therefore not a practical therapeutic method for the newborn infants nor does the medication of the mothers with sulfonamides necessitate the suspension of breast feeding. Excepting on the days when lactation begins the concentration of the sulfonamide compounds in the milk decreases below that of the blood as the puerperium progresses. Sulfanilamide, sulfapyridine and sulfa-acetylamide are exceptions. The excretion of the sulfonamides in the milk varies with the administered derivative. The authors observed that it is greater in milk than in blood, in decreasing order, in sulfa-acetylamide, sulfapyridine and sulfanilamide and inferior in milk than in blood in the other derivatives. The conjugation in milk is greater in sulfanilamide, then follow sulfanilylmethyl-sulfanilamide, sulfathiazole, sulfa-acetylamide, sulfapyridine and sulfapyrimidine. With sulfadimethylsulfanilamide the authors obtained only traces.

*Citric Acid in Blood Serum as Sign of Lesion of Hepatic Parenchyma in Heart Disease G Somolinos d'Ardois—p 53

Citric Acid in Blood Serum in Heart Diseases—Somolinos d'Ardois made quantitative determinations of citric acid in the blood serum of 30 patients with heart disease. These were placed in four different groups: (1) patients without decompensation, (2) with decompensation of about one month duration and (3) and (4) with intermittent and chronic decompensation, respectively. Sjostrom's index was used for the quantitative determination of citric acid in blood and Sjostrom's citric acid tolerance test was utilized as well. The liver was normal in 7 of 8 patients in the first group, moderately enlarged, hard and painful in 6 patients in the second group and greatly enlarged, hard and painful in the 16 patients who made up the third and fourth groups. The amount of citric acid in the blood was normal for all patients in the first group but 1 who had hepatitis and a slight increase of citric acid in the blood. It was normal or slightly increased for all patients in the second group. It was irreversibly increased for all patients of the third and fourth groups. The acid citric tolerance test gave negative results for all the patients in the first group, slightly positive for all patients in the second group and strongly progressive positive for all patients in the third group and strongly fixed positive for all patients in the fourth group. The author found by necropsy that hyperaciditricemia is due to anatomic lesions of the liver. It is proportional to the acuteness of the hepatic lesion and is not related to the degree of heart decompensation. He advises that the test be carried on in the course of heart disease for the diagnosis of the condition of the liver. The test is simple and reliable.

*Thrombosis of Primary Carotid Artery T Fracassi—p 1004

Thrombosis of the Common Carotid Artery—Fracassi reports a case in which a clinical diagnosis of thrombosis of the common carotid artery with complete occlusion was made. No clinical diagnosis of this condition has been previously reported in the literature. In the case reported by Wohlwill, necropsy revealed syphilitic aortitis with thrombosis of the common carotid at the point of its origin. The communicating posterior artery of the opposite side was so greatly dilated that an adequate collateral circulation had been established to take care of the occluded side. Fracassi's patient, aged 58, had a chancre in his youth. The chancre disappeared without treatment. The patient at no time exhibited syphilitic, circulatory or nervous symptoms. At the examination it was found that he had suffered for about three months from intermittent attacks of local pallor and coldness of the right hand and foot. There was also an attack of apoplexy with coma of ten hours' duration, transient aphasia and right hemiplegia. The patient complained about pulsation and pain in the region of the right temporal artery and its branches which did not yield to analgesics. The heart was normal. The pulse was normal, with a maximal tension of 100. The Wassermann reaction was positive. Bismuth and mercury therapy was administered. Three years later the patient was in a satisfactory state of health with normal intelligence and normal speech. An aortic murmur was audible. The roentgen shadow of the aorta was widened. The electrocardiograms showed changes in the myocardium. The left common carotid artery and its internal and external branch and the left temporal, angular and facial arteries did not pulsate. The right common carotid and its branches pulsated strongly. Blood pressure in the radial artery of the right side was 115, while in the left it was 100. The caliber of the retinal vessels of the left eye was narrowed. There was normal pulsation in both pedal arteries. There was a right sided hemiplegia and a deep and superficial anesthesia of the same side. A clinical

diagnosis of thrombosis of the common carotid artery was made. The hemiplegia was caused by softening of the brain tissue in the region of the left sylvian artery. The dilatation and forced pulsation of the right local arteries, on the one hand, and the narrowing of the left retinal vessels, on the other, confirmed the diagnosis. The author emphasizes the diagnostic significance of the absence of pulsation in the temporal and carotid arteries of one side and of forcible pulsation of the arteries of the opposite side in hemiplegia. These changes indicate thrombosis of the primary common carotid artery.

Problem of Ligation of Veins in Puerperal Pyemia After Thrombophlebitis of Pelvic Veins K Uhlenbrock—p 152

Radium Treatment of Cervical Carcinoma—Winkhofer points out that the irradiation of operable cervical carcinoma is regarded by many as not justified. He discusses the results of irradiation alone and of elective treatment citing collected statistics comprising thousands of cases and statistics from his own clinic (Heidelberg). He gained the impression that the irradiation of all cervical carcinomas yields results that are as favorable as those of elective therapy. He admits, however, that although at his clinic surgical treatment has been replaced more and more by irradiation vaginal and abdominal radical operations are still carried out occasionally, but the percentage of surgically treated cases is now much smaller than it was at the time when the elective treatment was in use. Until 1930 the single dose radium therapy was employed at the author's clinic, but since then it has been replaced by the fractionated usually two stage radium application. Fractionation has exerted a favorable influence on the morbidity figures. The partial arrangement of the radioactive substance is important because it determines the irradiation intensity at certain points of the tissue. Whereas in the period of one stage irradiation the ratio of the uterine and vaginal doses was about 1 to 1, it is now 1 to 2, that is one third of the radioactive substance is placed in the uterus and two thirds in the vagina. If the radioactive substance is applied uniformly to the vaginal plate the adjoining organs rectum and bladder are likely to develop severe indurations and cicatrizations. Now the radioactive tubes are placed chiefly in the marginal portions of the vaginal applicator, that is, they are directed toward the parametrium. In this way the cervical canal still receives the necessary carcinoma dose, but the injurious effect on the healthy adjoining organs is avoided. Fractionated irradiation having been in use only a comparatively short time figures about complete cures are not available. Observations so far indicate that the results will be not less favorable than when the single dose radium therapy was employed.

Synthetic Tocopherols (Vitamin E) as Activators of Progesterone—Stahler and Kaiser state that, of 14 women who had had from two to five abortions and were treated with the combination of small doses of progesterone and vitamin E, 13 gave birth to healthy children. Other investigators obtained favorable results with this combined administration of progesterone and vitamin E. The progesterone and vitamin E are given in comparatively small doses but over long periods, from twenty to thirty-two weeks. The authors report experiments on 30 female rats. In infantile animals that had been kept on a diet deficient in vitamin E a certain phase in the uterine mucosa could be obtained with one tenth of the dose of progesterone, when large doses of synthetic alpha tocopherol were given simultaneously. The histologic demonstration of glycogen in the uterus, as a specific corpus luteum action according to I A Miller, could likewise be demonstrated with much smaller quantities of progesterone, when alpha tocopherol acetate was given by mouth. The effect was less when the

vitamin was injected. Animals which were under the influence of vitamin E showed an increased activity of the ovaries. The hypophysis showed no noticeable changes on staining with Mallory's technique. Alpha tocopherol acetate caused a noticeable decrease in body weight after one day of its oral administration; animals lost 5 Gm, whereas a day of fasting reduced their weight by only 2 or 3 Gm.

Quantitative Modification of Progesterone Effects by Synthetic Tocopherols (Vitamin E).—Stahler and Pehl demonstrate that vitamin E (alpha tocopherol acetate) promotes the effect of both female sex hormones. In the case of the estrogenic hormone this effect is slight, but the action of the corpus luteum hormone is greatly intensified. Best effect is obtained when two thirds of the customary dose of corpus luteum hormone is given simultaneously with large doses of vitamin E. The weight increase observed in female rabbits in the course of the experiment seems to be caused by the progesterone. When vitamin E is given to female rats they suddenly lose weight, but this loss is rapidly made up again. It appears that the alpha tocopherol acetate has to be given for at least five days before its intensifying effect becomes manifest. Its effect is most intense after thirteen days of administration. Alpha tocopherol acetate has a stimulating effect also on the maturation of the primordial follicles in the ovary. Tests of the urinary elimination of hormones of the anterior lobe of the hypophysis in female rats did not yield positive results.

Arteriography in Aneurysms H Kilian—p 119

Arteriography in Aneurysms.—Kilian points out that the war has caused an increase in traumatic aneurysms. Many of these cases were treated at his clinic and he is able to describe a number of arteriographic visualizations of aneurysms, before and after operation. He reports about 15 aneurysms, of which 12 were resected and were cured either by direct suture of the vessel or by transplantation of the vein. Only 1 of the 15 patients died. Arteriography in the form of direct filling proved extraordinarily helpful. The puncture of an aneurysm involves no danger. The statements of Lohr and Christ about deficient filling of aneurysms can be regarded as surpassed. Arteriography is the most important procedure for testing the success of a vascular suture. The author presents in a table the hitherto observed cases of aneurysms of the common iliac artery and of the external iliac artery. The table lists the author who reported the case, the diagnosis, the operation and the result. Kilian also reports experiences at his clinic with vascular suture following extirpation of aneurysms and the treatment of the circulation during these interventions. The success in such operations on the large vessels depends largely on the skill and experience of the surgeon. For this reason the aneurysms caused by war injuries should be collected in a few selected clinics where surgeons are available who are experienced in their treatment.

Treatment of Furunculosis Particularly of Miners Furunculosis A Mohlenbruch—p 1158

Treatment of Furunculosis in Miners.—Mohlenbruch directs attention to the high incidence of furunculosis in coal miners. The average incidence in the Ruhr region was 1.45 per cent and in one group of miners over 2 per cent. Occupa-

tional factors which reduce the miners' resistance to cutaneous infections doubtless play a part in the pathogenesis. It is suggested that the high salt content of water in the mines, dampness and high temperatures favor the development of furunculosis. The customary treatment by incision, ichthammol ointment and plasters accelerates the healing of the individual furuncle but does not prevent the development of additional furuncles. The author resorted to a general treatment with a mixed vaccine containing antigens of staphylococci, streptococci, pneumococci, pyocyanus and colon bacilli. It also contains some nonspecific lipoids and proteins. The authors used this vaccine in 28 moderately severe and severe cases of furunculosis. In the moderately severe cases three intramuscular injections at two or three day intervals were usually adequate to effect cure. In the severe cases two or three additional injections were required. The treatment was ambulatory, was always well tolerated and caused no undesirable secondary effects. The vaccine treatment is superior to local treatment. It causes a rapid disappearance of small foci and liquefies the contents and causes evacuation or resorption in the larger lesions and thus reduces loss of tissue. Prevention of relapses after the vaccine treatment indicates that immunity is favorably influenced.

Valvular Pneumothorax by Bilateral Pneumothorax Case K A Vannfall—p 265

Effect of Sulfonamides on Thrombocytes and White Blood Cells in Rabbits.—Lindelof found that, in rabbits, (1) a sulfonamide derivative in the dosage of 0.11 Gm per kilogram of body weight causes a tendency to thrombocytosis and weak polymorphonuclear leukocytosis together with a slight monocytopenia, (2) sulfapyridine in the dosage of 0.008 Gm per kilogram of body weight has no certain effect on the thrombocytes and white blood corpuscles, (3) sulfathiazole in the dosage of 0.0075 Gm per kilogram of body weight causes a weak thrombopenia and may cause a moderate leukocytosis, and (4) azosulfamide in the dosage of 0.187 Gm per kilogram of body weight leads to an initial slight thrombocytosis and a slight polymorphonuclear and monocytary leukocytosis.

Action of Peroxidase in Blood Plasma in Acute Infections.—Mollerstrom states that in acute infections the leukocytes probably play an important part as the source of peroxidase substances, which are released on degeneration of the leukocytes and appear in soluble form in the blood plasma. It is possible that an increased production of hydrogen peroxide on increase of the oxidation processes leads to a greater need of peroxidase substance. If this is present the oxidation processes are further increased. Thus besides their phagocytizing action the most important function of the leukocytes in infections may be the production of peroxidase substances and giving them off to the plasma and to the cells and tissues, by which the defensive powers of the organism against the infection are heightened. Digestive leukocytosis probably serves a similar purpose. The author adds that the peroxidase action in the blood plasma established by his clinical investigations may depend on verdoperoxidase which was isolated from leukocytes by Agner in 1941. According to Agner up to 1 or 2 per cent of the dry substance in the leukocytes is verdoperoxidase.

Book Notices

Manual of Standard Practice of Plastic and Maxillofacial Surgery Prepared and Edited by the Subcommittee on Plastic and Maxillofacial Surgery of the Committee on Surgery of the Division of Medical Sciences of the National Research Council and Representatives of the Medical Department U S Army Robert H Ivy Chairman Volume 1 Military Surgical Manuals Cloth Price \$5 Pp 432 with 250 illustrations Philadelphia & London W B Saunders Company 1942

This book is the first to be published of a series of six volumes comprising twelve military surgical manuals. The series is being developed under the auspices of the Division of Medical Sciences of the National Research Council to furnish the medical departments of the United States Army and Navy with compact presentations of necessary information in the field of military surgery. The individual manuals are prepared under the auspices of the various subcommittees of the Committee on Surgery of the Division of Medical Sciences of the National Research Council, and the manuscript editing is done by the Committee on Information.

The series of books of which this volume is the first apparently are not pocket manuals to be taken to the front line or wherever the equivalent of the front line is in modern warfare. Most of them deal with highly specialized surgical subjects. They seem designed to help the surgeon, well qualified in some other field perhaps, who suddenly is faced with the necessity of applying his skill in a field not strictly his own. The books, then, presumably will be found on shelves in training centers in the more permanent installations of the army and on ships and in shore stations of the navy.

The volume under consideration here will serve an even more particular function than that just expressed. It is truly a manual of standard practice divided into four sections respectively on reconstructive surgery, maxillary surgery, maxillofacial prosthesis and anesthetic techniques.

Appropriately 65 per cent of the book is given to the section on reconstructive surgery, which subject is taken up under the headings general considerations, condensed discussions, cheiloplasty, meloplasty, rhinoplasty, blepharoplasty, otoplasty, defects of the scalp and cranium, cervicoplasty and loss of the hard palate and premaxillary portion of the alveolar process. The material under the first two of these headings deals mainly with underlying principles and general methods, the application of which in particular regions is explained under the succeeding headings. It is a good plan, well executed.

The section on maxillary surgery appears in two chapters entitled gunshot wounds involving the jaws and fractures of the jaws. This and the succeeding sections on maxillofacial prosthesis and anesthetic techniques are as well done as the first section but, since they are briefer and simpler in organization they require less comment here.

Apparently special effort was made to bring out all possible details of the carefully chosen illustrations. To this end a coated paper, heavier than that which, it is reported, is designated for use in succeeding volumes, was employed. The result has been excellent in almost all cases, and thus what may be the most uniquely valuable feature of this book has been preserved. That is, the volume might almost be classed as an atlas of plastic and maxillofacial surgery. There are two hundred and fifty-seven numbered illustrations in the manual. Many of them are multiple, however, and if the many parts of the multiple illustrations are counted individually, the number rises to almost nine hundred. The advantages of such a book as a teaching manual are obvious.

Feeding the Nation in Peace and War By George Walworth M A Dip Agric Cloth Price \$5 Pp 548 New York W W Norton & Company Inc London George Allen & Unwin Ltd 1940

The national nutrition is giving Great Britain even more concern than it is giving us, because they have many more problems than we do. In the practical approach to these problems, books like that of Walworth are invaluable. He is concerned not so much with the medical aspects of nutrition as with agricultural and economic problems. His book provides an

analysis of the nutritional situation before the great war, with a complete study of marketing experiments in foods and a study of attempted control of the meat supply, the wheat supply and the dairy supply, with special chapters on potatoes, sugar, eggs and poultry and a concluding chapter on the problems of feeding the nation in peacetime and in wartime. The author is seriously opposed to economic nationalism and feels that peace can never be won if attempts are made by producers to enforce continuance of high price policy. Mr Walworth favors competition in production, distributing, wholesaling and processing, provided the government lays down and maintains rigidly standards for every stage in the field. He says "The real requirement was not accumulation of capital, establishment of reserves and large working interest in terms of unstable and no longer genuine international value, but reliable food for the nation and, in exchange, British manufacturing production to provide employment and a good healthy standard of living. Instead of this, there arose a universal mass of legislation to prevent humanity from enjoying the fruits of the earth and the profits of industry."

Apparently the British government has been none too successful in its attempt to manage the food situation. Mr Walworth says "In spite of all previous experience, however, the government is obsessed with the importance of managing everything in the country on a national scale, commenced by taking actual control of imports and raising prices of imported foods near to the level of home produced commodities." Mr Walworth feels that the approach has been wrong in that the attempt is made to guarantee a profit to every one along the chain of food production, distribution and utilization. He feels there is no inherent reason why a more organization of food supplies should lead to losses for producers or traders. Nourishment of the people is so important for the nation as a whole that efficient production and efficient marketing of essential foods should be considered as part of the national program and proved losses might be made good by the state.

There may still be justification for civilized communities to indulge in the barbarism of warfare in order to deal with barbarians but there is no justification for a civilized community to tolerate malnutrition within its own boundaries. The cost of eliminating malnutrition is a small fraction of the cost of conducting modern warfare. How long then will the needy and the oppressed within our own country be compelled to suffer the torture of undernourishment? The problem of feeding the nation is the problem of re-creating the nation in order to demonstrate in practice all that is noblest and best in civilization.

Architectural Principles in Arthrodesis By H A Brittain M A M Ch F R C S Senior Orthopaedic Surgeon Norfolk and Norwich Hospital and Jenny Lind Hospital for Children With a foreword by Harry Platt M D M S F R C S Professor of Orthopaedic Surgery University of Manchester Manchester Cloth Price 6s Pp 132 with 144 illustrations Baltimore William Wood & Company 1942

This interesting book is built around a specific type of operative procedure which is one of the most interesting of all bone and joint surgery—the solidification or fusion of joints by artificial means—surgery. The author makes a definite departure from the ordinary treatment of similar material. He approaches the subject as it might be discussed by an engineer, a carpenter, a cabinet maker or a builder of bridges. He employs the general principles of biomechanics, dynamics and engineering. The book reflects the mechanical point of view applied to a biologic subject.

The author has evidently not been satisfied to continue with routine stereotyped operative procedures for arthrodesis but has used his brain to devise new procedures. He discusses the indications for arthrodesis, the causes of failure and the technical principles involved. The indications for arthrodesis are tuberculosis, infectious and rheumatoid arthritis, osteoarthritis with degeneration as the result of trauma, infantile, spastic and traumatic paralyses, and certain congenital deformities. The chief causes of failure of fusion are inadequate apposition, incomplete immobilization, extension of the disease and operations conceived on false mechanical premises. The first elementary principle of architectural success is that the graft should be placed with its long axis under compression rather than in tension. The second principle is that the breadth of the graft should be placed in the position of maximum stress. The third principle

is that a joint should be locked by two grafts crossing each other in the shape of the letter X. The fourth is that there should be adequate protection of the graft.

Brittman advocates a straight graft from the medial surface of the tibia not including the crest. The second type of graft is massive—consisting of the entire medial surface of the tibia. The third is the elongated bial graft with a step at each end called the arrowgraft. The fourth is a single bial graft. The fifth is a twin graft cut from the upper third of the tibia. The sixth is the arrowgraft. The seventh is the clip graft.

The author's main point of view has been the ankylosing of joints rendered useless or even a detriment by disease or degeneration. This would include especially tuberculous and arthritic joints. One is unable to detect sufficient evidence of the author's interest in joints rendered ineffective by infantile paralysis, although these are briefly mentioned.

Mr. Harry Platt, one of the leading orthopedic surgeons of England, states in the foreword that one of Mr. Brittman's notable contributions is his operation of ischiofemoral arthrodesis, in which Calvé's prediction has been fulfilled that some day the tuberculous hip joint would be successfully fused by constructing a buttress on the adductor side of the joint.

The illustrations are by Kidd and are truly beautiful and just as instructive. The artist uses diagrams very effectively without loss of important anatomic landmarks.

The Modern Attack on Tuberculosis By Henry D. Chadwick, M.D., and Alton S. Pope, M.D., Deputy Commissioner of Public Health and Director of the Division of Tuberculosis, Commonwealth of Massachusetts. Cloth. Price \$1.10 with 5 illustrations. New York: Commonwealth Fund, London: Oxford University Press, 1942.

Here is an excellent discussion of all phases of tuberculosis control work. The authors call attention to the decline of tuberculosis in the United States, which has been almost continuous since 1842. They believe that two main procedures contribute largely to this decline: (1) the almost complete elimination of tuberculosis in the dairy cattle and (2) the focus of attention on the infectious human being. They point out, however, that little substantial progress has been made in finding cases of early tuberculosis, probably because of the lack of symptoms in this stage of disease. The authors emphasize the importance of reporting cases to the health department. They present evidence to show that among white patients not more than one half of the actual cases are reported.

One is left with the impression that the authors consider the tuberculin test of little importance in mass survey work among adults. They have worked where the majority of adults are infected. However, in vast areas of the country in the Middle West and West the majority of adults have not been infected and therefore the tuberculin test is of extreme value in individual examinations as well as in mass surveys.

The authors call attention to the former limited use of roentgenograms because of expense. They then discuss the attempts to reduce the cost of this phase of examination and point out that, while the fluoroscope is of great value, it is economical only for the examination of large groups and gives no permanent record. They have saved considerable sums of money by substituting 14 by 14 inch films for the usual 14 by 17 inch film. This smaller film is large enough for nearly all women and for at least 75 per cent of the men. Attention is called to the paper film available in standard sizes, which, they believe, provides for the necessary diagnostic qualities. Their only objection to this film is its tendency to curl in drying, an objection which has been overcome. They consider that the 4 by 5 inch fluorograph and microfilm are still too recent to permit any final evaluation of their application in the diagnosis of pulmonary tuberculosis. At the same time they present the evidence that is now available both for and against photofluorograms.

A large number of clinicians in this country will not agree with the statement that roentgenograms have "replaced to a large extent all other diagnostic procedures" or with the statement that the low cost x-ray film should be used for screening purposes without having recourse to the tuberculin test. Probably all clinicians who use the x-ray film extensively will agree with the statement that evidence of disease in the lungs

can often be detected on the x-ray film long before symptoms and signs of the disease appear or can be detected. Most clinicians will insist that the finding of evidence of disease in this manner is only one step toward the diagnosis and that the etiology of the disease which casts the shadow must be determined by other methods.

Emphasis is placed on the sanatorium as a means of controlling tuberculosis, where the public is protected from infection while treatment is administered. They show that the 90,000 patients occupying beds available for tuberculosis in this country cease to be a menace to the community during the period of isolation and that about 25 per cent of these patients are in a hopeless condition on admission and die in the sanatorium.

Collapse therapy, particularly artificial pneumothorax, is given the important place it deserves in the treatment of tuberculosis. However, many physicians who have so successfully employed ambulatory artificial pneumothorax in carefully selected cases will not agree with the discouraging statements made concerning this form of treatment.

The treatment of primary tuberculosis in children is discussed and the authors state that "since there is no demonstrable proof that hospitalization of children has any effect on the subsequent development of the lesion in most cases, no special treatment other than good care and separation from sources of infection is needed for this age group." However, they emphasize the fact that with the approach of puberty and during the period of adolescence the "danger period sets in." They also insist on immediate treatment when clinical pulmonary tuberculosis is found in this age period and are of the opinion that artificial pneumothorax should be instituted at once, even in minimal cases.

They emphasize the importance of special measures to protect both medical students and nurses during their contact with tuberculosis and point out that similar precautions should be taken for other members of the sanatorium personnel.

The authors make the extremely significant statement: "We need not wait for the chemists or biochemists to produce a specific that will inhibit or cure the disease but may proceed at once to make the best possible use of the defensive and offensive weapons that now are available."

The final chapter, entitled "A Community Campaign of Eradication," presents an excellent method of procedure. Slight modifications with reference to tuberculin testing and so on will be necessary in parts of the country where the prevalence of tuberculosis is definitely less than in some of our Eastern cities and states. This is a splendid book and should be read by every physician.

Carlos Finlay and Yellow Fever By Carlos F. Finlay, M.D., F.A.C.S., Professor of Ophthalmology of the University of Havana, Havana, Cuba. Edited by Morton C. Kahn, M.A., Ph.D., Sc.D., Associate Professor of Public Health and Preventive Medicine, Cornell University Medical College, New York, N.Y. Published under the auspices of The Institute of Tropical Medicine of The University of Havana. Cloth. Price \$4.00. 249 with 26 illustrations. New York: Oxford University Press, 1940.

As the author explained in the foreword, this book was written at the suggestion of Dr. Morton C. Kahn in order to place on record in an English publication many facts that are not well known about the life and work of his illustrious father. The son has had available a mass of documentary evidence which proves conclusively that the elder Finlay as early as 1881 discarded all other theories of transmission of yellow fever and advanced that which was later confirmed by the United States Army Yellow Fever Board. Not only did he advance a theory based on careful scientific reasoning but he actually reproduced the disease in human subjects to the number of sixteen in one hundred and two trials by 1900. That it required the work of the Yellow Fever Board to prove the etiology should not detract from the importance of Finlay's contributions, for they in turn furnished a substantial basis on which the board could initiate the work. Finlay's theory was apparently constructed independently of the earlier suggestions of Nott and Beauprethys that the disease was transmitted by the mosquito, suggestions that were not supported by any investigation. Aside from its historical value the book is an excellent brief treatise on the epidemiology of yellow fever.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

SENSITIZATION BY BLOOD TRANSFUSION

To the Editor—Is it possible to sensitize a person receiving a blood transfusion so that an anaphylactic reaction or serum disease may result if the patient receives another transfusion of blood from the same donor after a certain critical interval of time? Have such reactions ever been recorded in the literature?
D I Macht M.D. Baltimore

ANSWER—It is possible to sensitize a person by blood transfusion so that a shocklike reaction may occur when another transfusion is given after a critical interval. This can occur even though the patient and donor belong to the same blood group.

Reactions in patients receiving repeated blood transfusions may be caused by sensitization either to antigens contained in the erythrocytes or to antigens in the plasma. The former type of sensitization, giving rise to hemolytic shock is by far the more common, the antigen most frequently responsible being the so called Rh factor (Wiener, A. S., and Peters H. R. Hemolytic Reactions Following Transfusions of Blood. *Ann Int Med* 13 2306 [June] 1940. Wiener, A. S. Hemolytic Reactions Following Transfusions of Blood of the Homologous Group. *Aich Path* 32 227 [Aug.] 1941). In such cases as a rule the patients are Rh negative and as a result of transfusions of Rh positive blood immune anti Rh isoantibodies are formed. Many authentic cases of sensitization to the Rh factor have been observed since the original report by Wiener and Peters appeared.

Sensitization to substances in the donor's plasma based presumably on individual differences in plasma proteins, appears to be extremely rare (Wiener A. S. Blood Groups and Transfusion ed 2, Springfield, Ill. Charles C Thomas, 1939, p 104). In fact, some authors question the existence of such an entity as "proteolytic shock" and state that deaths ascribed to this mechanism are probably more likely due to the too rapid injection or the injection of too much blood ("speed shock"). Hirschfeld Samuel, Hyman, H. T. and Wanger Justine J. Influence of Velocity on the Response to Intravenous Injections, *Arch Int Med* 47 259 [Feb.] 1931). However, Blottner (*Deutsche med Wchenschr* 50 599, 1924) and Traum (*Deutsche Ztschr f Chr* 257 97, 1932) have reported instances of shock after repeated transfusions of blood from the same donor. Gyorgy and Witebsky (*Munchen med Wchenschr* 195 [Feb 1] 1929) reported that an 8 year old child of group O received transfusions of group O blood from its father and mother, twenty days later, when the child was transfused again with its father's blood signs of severe anaphylactic shock appeared. It was found by cutaneous tests that the child was sensitive to the father's serum but not to the mother's, and the child's serum also gave positive complement fixation with the father's serum. This may indicate that the child had become hypersensitive to some individual specific substance in the father's serum or merely that the child was sensitive to some foreign food circulating in the donor's blood stream.

With the widespread adoption of serum and plasma transfusions in recent years, it might be expected that cases of sensitization with resulting proteolytic shock should occasionally be encountered. It is significant that, while urticarial reactions are not uncommonly seen, no case of shock that can be explained on this basis has been reported.

CONGENITAL BOWING OF LITTLE FINGER

To the Editor—Will you kindly give the treatment for congenital inward bowing of the fifth fingers in a 7 month infant?

Samuel Lewis M.D. Brooklyn

ANSWER—Bowing of the fifth finger is a rather common congenital abnormality, usually requiring no treatment. In severe cases corrective osteotomy of the phalanx may be done when growth of the phalanges has been completed. Sometimes splints are applied. Their efficacy in correcting the deformity however, is doubtful. In a young child with no functional impairment of the hand it is best to apply no treatment.

ASYMPTOMATIC CONGENITAL SYPHILIS

To the Editor—I disagree with the reply to the query submitted by M.D. Indiana regarding the question of further antisyphilitic therapy for an 'asymptomatic congenitally syphilitic' 13 year old girl with a persistently positive blood Wassermann reaction (The Journal July 11 1942 p 910). Instead of commenting on the fact that the girl had already received the alarming total of somewhere near a hundred and five arsenical and sixty seven heavy metal injections over the equally alarming period of five years the reply actually advised an additional sixty doses of bismuth. Syphilologists have been aware for many years that a persistently positive Wassermann reaction in a patient with late latent syphilis particularly congenital syphilis does not justify more than a moderate prolongation of the recommended routine total treatment program and does not warrant any particular pessimism regarding the prognosis. It should not be necessary to comment on the distinction between latent and asymptomatic which are of course by no means synonymous states. In a congenital infection perhaps the most important distinction between the two may lie in the spinal fluid findings which were mentioned in neither the query nor the reply.
Harry L. Arnold Jr. Honolulu Hawaii

ANSWER—The criticism is justifiable with regard to the need for examining the child's spinal fluid, as such a suggestion should have been incorporated in the answer to the original inquiry. If the test is positive, fever therapy would seem indicated while, if it is negative the continued use of bismuth as suggested should be followed.

With regard to the rest of the comments, it would appear that the commentator is confused in distinguishing 'latent' and 'asymptomatic' and in not recognizing the different therapeutic requirements of latent acquired syphilis and latent congenital syphilis.

The treatment that this 13 year old girl has received may be considered adequate but not intensive in view of the fact that it was spread over a period of five years. The amount of arsenic and heavy metal that she was given in five years is not an unusual amount of therapy for a girl with congenital syphilis and is the type of program that should be considered for every child, especially a girl, with this disease. The reason for continuing with further bismuth therapy now at the rate of two courses a year is to prevent if possible clinical progress of the disease in the form of interstitial keratitis, nerve deafness and the like which are prone to appear as these youngsters approach or pass through the period of puberty. Accordingly, further bismuth therapy is justified for this young patient in an effort to keep her well rather than to place her on observation to await the development of a serious complication. There is no set rule as to when treatment may be stopped of a child with congenital syphilis, and recognized authorities usually continue the treatment until the child, especially a girl, is well matured.

The terms 'latent' and 'asymptomatic' are used interchangeably and are accepted as synonymous by the majority of syphilologists as both terms are applied to that phase of the disease when clinical signs and symptoms are lacking and the diagnosis is made on serologic evidence only. Whether the patient remains asymptomatic or remains permanently the state of latency can be determined only by an indefinite period of observation.

FACIAL DERMATITIS IN INFANTS

To the Editor—Is nonparasitic facial dermatitis of infants a metabolic disturbance? Is it caused by an excess of sugar in the diet or possibly an excess of vitamins B or D? What diet is recommended and what is the value of solution of potassium arsenite administered internally? Also what is the value of ascorbic acid and external application such as Lassar's paste and calamine lotion? Will you kindly give me the name of some good book on this subject?
A. N. Chotel M.D. Detroit

ANSWER—As the result of seventeen years of study of infantile eczema in Germany and the United States, Tachau (Problems of So Called Infantile Eczema. *Acta dermat venereol* 19 587 [Nov.] 1938, 20 42 [Feb.] 232 [Mar.] 1939) explains the facial dermatitis of infants and children as either contact dermatitis atopic dermatitis or seborrheic dermatitis. They all involve the face much more frequently in infants than in older persons. In infants less than 1 year of age, 57 per cent of all those with eczema had involvement of the face and during the second year of life 59 per cent had the face involved while in older children the face was chiefly involved in only 30 per cent.

Contact dermatitis Tachau considers true eczema. It is caused by sensitization to such common irritants as sunlight, water soaps, cosmetics, primrose, imitation leather and the substances used for stuffing cushions.

For the second subdivision of dermatitis of infants Tachau adopts the name atopic dermatitis, suggested by Hill and Sulzberger (Evolution of Atopic Dermatitis, *Arch Dermat & Syph* 32 451 [Sept.] 1935). It has been known as lichen simplex chronicus or neurodermatitis but was renamed after Coca's definition of atopy as a familial disease characterized by allergy usually to multiple substances, causing hay fever, asthma, derma-

titis, migraine or gastrointestinal disturbances. Tachau applies the term to the localized as well as the generalized form of cutaneous involvement for he has seen helen simplex change to the generalized form and has seen generalized neurodermatitis quiet down, leaving only a few areas of chronic involvement. He also objects to the limitation to dry, hyperkeratotic eruptions, for in infants the lesions are often moist at first corresponding to the first stage described by Hill and Sulzberger. Tachau finds that this form of infantile dermatitis is much more prevalent in the United States than in Europe forming here the major part of the disease called infantile eczema.

None of these diseases are known to be due to an excess of sugar in the diet or of vitamins B or D. The sugar theory was formerly held for scabrous dermatitis but is not now believed. Diet is of importance in some cases but not nearly as often as was formerly thought. It has to be regulated in accord with the general needs of the infant. There is no eczema diet. Solution of potassium arsenite is of value as a tonic. Ascorbic acid is of great importance in all cases of sensitization as shown by Sulzberger and Oser (Influence of Ascorbic Acid on the Sensitization of Guinea Pigs to Neoriphenamine *Proc Soc Exper Biol & Med* 32 716 [Feb.] 1935). They found that animals on a winter diet low in vitamin C could be easily sensitized to the drug 75 to 100 per cent of them proving susceptible while those on a summer diet containing the vitamin were susceptible in only small numbers, 0 to 12 per cent. This problem in relation to the management of infants is discussed by C. J. Farmer (Vitamin C Analysis in Relation to Clinical Problems *Quart Bull North Eastern Univ W School* 14 220 1940). The danger of a vitamin C deficiency is greater in infants than in adults particularly in association with gastrointestinal disease.

External applications are of great importance. It is particularly valuable to know the conditions calling for any form of local treatment and when such local applications must be changed. Calamine lotion is useful for soothing and drying, but its tendency to form adherent crusts sometimes leads to fissure formation and it is necessary to use a starch poultice or wet dressings of boric acid solution or Burow's solution to alternate with the calamine lotion. Lassar's plum zinc paste, paste of zinc oxide N F (without salicylic acid), is one of the most useful agents for the treatment of dermatitis in infants.

INTRAOCULAR HEMORRHAGES IN DIABETES

To the Editor—A man aged 39 with diabetes mellitus of two years standing is rapidly losing his vision in both eyes because of intraocular hemorrhages. I would appreciate any references or help you can give me regarding prevention of further hemorrhage or resolution of hemorrhages that have already occurred and also regarding the prognosis from the standpoint of blindness as well as the diabetes in general. In this case focal infections of the teeth and tonsils have been ignored to date. Is it true that these infections have no bearing on intraocular hemorrhages in a diabetic patient? M D Missouri

ANSWER—The hemorrhages usually seen with diabetes mellitus are of the tiny punctate variety involving the macular area. They usually appear in diabetes of long standing most often when patients are not well controlled. The flame shaped hemorrhages and the larger hemorrhages which frequently lead to a proliferating retinitis are more scattered and extensive and are frequently associated with an accompanying nephritis. Even the small punctate varieties are not infrequently associated with small exudates which seem to come and go giving transient improvement in vision. As the condition progresses, and in the more severe form an optic neuritis followed by optic atrophy may terminate with blindness. The proliferating retinitis often produces detachment of the retina and blindness.

There is no specific treatment for the condition. It is most essential to regulate the diet and keep the patient entirely sugar free. Saturated potassium iodide taken internally as well as ascorbic acid and vitamin B complex have been used in an effort to promote absorption.

CHEWING TOBACCO

To the Editor—Is there any drug to apply to chewing tobacco which might discourage a young boy from the habit of chewing it? M D West Virginia

ANSWER—Although the addition of bad tasting or nauseating drugs to chewing tobacco (quinine, ipecac) might make chewing tobacco immediately distasteful or even set up conditioned reflexes against it, the effect might be short lived and set up undesirable antagonisms. Substitution of chewing gum or other material may be tried. Psychologic and sociologic factors may be more important in reinforcing or overcoming the habit.

OPERATIVE INJURY OF THORACIC DUCT

To the Editor—A woman aged 52 stated that several weeks ago she noticed a lump over her left collar bone. It did not cause her any distress or any pain. Examination revealed a walnut sized, fairly mobile circumscribed tumor in the left supraclavicular region immediately above the clavicle, about 1 inch lateral of the left sternoclavicular joint. She showed a severe secondary anemia but x ray examination did not reveal any disease in the lungs nor did it show any connection between the tumor and the joint and bone respectively. Considering her anemia and the fact that she had often been hoarse lately operation was decided on. A horizontal incision divided the skin and platysma muscles parallel to and above the left clavicle. The tumor was exposed. It appeared to be an enlarged lymph gland with a broken down upper part from which about 2 cc of pus was obtained the smear showing numerous lymphocytes but no tubercle bacilli. The base of the gland was closely adherent to the internal jugular vein. After the vein had been carefully isolated 1 inch of it was resected with the rest of the diseased gland. This was done about an inch and a half above the junction of the internal jugular and subclavian veins. No bleeding occurred and no lymph was visible. However a few days after the operation a large edematous area appeared around the wound which did not seem to be postoperative reaction and a fairly large amount of lymph was aspirated from the cavity which at the time of the operation was packed with iodoform gauze in order to obliterate the dead space left after the removal of the gland. The rest of the wound healed primarily but at the present time—ten days after the operation—there is still an extensive edema present and every day about 3 to 4 ounces of lymph can be aspirated from the wound. Is there any possibility that lymphorrhea will cease spontaneously? Can some medication be used which would promote healing or seal the apparently severed lymphatic duct or would roentgen therapy be of any benefit? Will it be necessary to reopen the wound in order to locate and ligate the left lymphatic duct in order to obtain final healing? M D New Jersey

ANSWER—Although the internal jugular vein was carefully isolated in this case and was resected about an inch and a half above the junction with the subclavian vein, the dissection was not unlikely to injure the thoracic duct. The arch of the thoracic duct may extend as high as 5 cm above the manubrium before the duct terminates in the subclavian vein.

Semken (Nelson's Loose Leaf Living Surgery vol 2 chapter 14, p 898) says 'The effect of injury to the thoracic duct is not uniform and in the majority of cases complete recovery takes place. In the mildest cases the small leakage soon ceases spontaneously, but in the severer cases the chylous discharge is very profuse, the patient shows the effect of the loss of fluid and nutrition (thirst, vertigo weakness and occasionally psychic disturbance) and if he is already debilitated, the injury will probably prove fatal unless the leakage can be checked promptly.'

It is highly improbable that any medication or irradiation will promote healing. On the other hand the flow may be diminished by a high protein, low fat diet.

Injury recognized during operation is handled most simply by fine suture or ligation. Injury recognized after operation should be treated at first conservatively. The wound flap should be compressed to prevent accumulation of chyle. If this does not succeed, the wound should be opened and packed with gauze. Semken suggests that a rubber dam be placed directly over the opening into the duct to minimize trauma when the gauze packing is removed. Packing in proximity to large veins in the neck is not without hazard. In addition to gauze packing cauterization is mentioned by Curtis in Christopher's Textbook of Surgery (ed 3 Philadelphia, W B Saunders, 1942 p 235).

If spontaneous closure does not occur, cauterization and packing are ineffectual, and if the patient's general condition deteriorates it will be necessary to dissect out the duct and ligate it. Location of the injured duct is facilitated by the administration of cream before operation which insures a more profuse flow of chyle. The mortality of the operation is reported as being between 5 and 10 per cent (Curtis). Implantation of the injured duct into the left subclavian vein has been described.

CLINITEST URINE SUGAR ANALYSIS

To the Editor—I have received literature pertaining to the Clinitest urine sugar analysis set sent by the Effervescent Products Inc of Elkhart Ind. Kindly inform me as to the reliability of this test in comparison with the usual urine sugar tests. C A Eisner M D, Pittsburgh

ANSWER—The Clinitest method for the determination of dextrose in the urine is a fairly accurate method. Its chief disadvantage is that the tablets are caustic and will cause severe burns if they come in contact with the skin, particularly if the skin is at all moist. Forceps or folded paper should be used in handling the tablets.

In checking results by this test against those obtained by the Millard-Smith modification of the Benedict quantitative method the agreement was good.

SEXUAL OVERDEVELOPMENT IN YOUNG BOY

To the Editor—Is there anything which can be done to counteract the overstimulation of the glands of internal secretion which control the production of secondary sexual characteristics? A boy aged 6 is perfectly normal in every respect for that age except that the penis is greatly enlarged and erections are frequent. There is no change in the testes or scrotum or voice. Pubic hair is beginning to show. There is no axillary hair as yet. Hair on the legs is becoming quite thick, stiff and dark. The condition is becoming embarrassing to the lad as his playmates make sport of him. I am afraid that this unless stopped will result in some sort of a complex which will be highly detrimental. M D California

ANSWER—Every effort must be made to exclude the existence of a tumor of the adrenal cortex or a pineal or hypothalamic lesion. Such evidence is often absent and the cause of the defect remains obscure. In such event if the social problems are not too serious no treatment should be undertaken. If they are so serious that the physician feels obligated to undertake frankly experimental measures an estrogen such as diethylstilbestrol might be used. The dose should be so regulated that gynecomastia is not added to the disabilities of the boy. The theory determining this experiment lies in the known capacity of estrogens to inhibit certain of the gonadotropic secretions of the pituitary body. The hazard lies in depression of testicular function. Recovery from brief treatment is clear enough, but there are no data concerning recovery from protracted treatment in the growing boy. It is also possible that disadvantageous epiphyseal changes affecting skeletal growth might occur. If treatment is regarded as sufficiently indicated despite these uncertainties, the child should be watched carefully and the experience of the physician made known to the rest of us.

OBSTINATE CONSTIPATION IN YOUNG WOMAN

To the Editor—A woman aged 28 having suffered from constipation practically all her life necessitating frequent enemas and laxatives developed mucous colitis in January of this year. The constipation remains and she has to take two or three warm water enemas daily to relieve the abdominal pain with these enemas she expels large amounts of mucus. Dieting belladonna phenobarbital diluted hydrochloric acid, atropine, short wave treatments and tincture of iodine each given at various times have not helped the condition. The patient weighs 93 pounds (42 Kg) and has lost about 8 pounds (3.6 Kg) since January 1942. All laboratory tests give essentially normal results. She is the only child in the family and is of a slightly nervous disposition. I would appreciate hearing from you what measures can be used in the treatment of this condition. I have recommended rest physical and mental but without any benefit. Is cecostomy indicated in such cases?

M G Ericsson M D Cedar Falls Iowa

ANSWER—A 28 year old woman with obstinate constipation may have nothing more than a psychogenic factor as the cause of her condition. All of the medical approach has been of no avail, and in this case a medical approach to the problem may well prove useless. She should be under the guidance of a psychiatrist. No surgical procedure should be undertaken at any time for constipation, except when there is a mechanical factor involved.

Another possibility is that she may be viscerotonic and if a suitable corset and pad to hold the stomach in normal position are procured, it might aid in her digestive disturbance. Sometimes obstinate constipation has been improved in thin, asthenic persons when the stomach has been held in normal position.

RECURRENT CROPS OF VERRUCA VULGARIS

To the Editor—Is there any acceptable method of systemic treatment for recurrent crops of verruca vulgaris to prevent recurrences? The standard textbooks all mention the use of heavy metals but are not enthusiastic about the results. If bismuth may be employed is oral medication with subminimal mass permissible?

Charles Hertzman M D, New York

ANSWER—Good results from the use of heavy metals in the treatment of verruca vulgaris will probably not be obtained. It is true that with verruca plana juvenilis the response to the use of mercury internally is excellent. It may be given in the form of yellow mercurous iodide tablets, 0.01 Gm, three times a day.

A good treatment for groups of verruca vulgaris is the use of the actual cautery to each lesion. Such a patient should be followed up at intervals of two weeks to catch any new lesions that are starting, for, after all, one is dealing with a filtrable virus infection, usually in a person who has no resistance to the disease.

Locally, it is not a bad plan, following the use of the actual cautery, to use weak mercury bichloride hot compresses for fifteen or twenty minutes, twice a day.

MENSTRUATION FOLLOWING SUBTOTAL HYSTERECTOMY

To the Editor—After subtotal hysterectomy leaving only the cervix what percentage of women will continue to have a menstrual flow? Specifically a patient aged 38 had an abdominal hysterectomy performed five weeks ago. The right ovary (cystic) was removed. Four days postoperatively (menstrual time) there was slight bleeding. A few days ago (menstrual time again) she had moderate backache and a menstrual flow for twenty four hours. The flow however, was more serious than preoperatively. Do you think she will continue to menstruate? M D New York

ANSWER—As far as is known there are no statistics concerning the incidence of menstruation following subtotal hysterectomy. Generally when a subtotal hysterectomy is performed not only is the entire corpus uteri removed but also a small portion of the cervix. Following such an operation periodic monthly bleeding almost never occurs. When, however, in performing the subtotal operation not only is the entire cervix left behind but also a small part of the body of the uterus periodic bleeding not infrequently occurs. This may persist for years, even as long as the ovaries retain their function. In other instances the bleeding ceases after a few months. In either event there is nothing pathologic about this phenomenon. In fact some women feel better if they have slight menses following a subtotal hysterectomy.

PUNCH BIOPSY

To the Editor—In the autobiography "Doctor Here's Your Hat" by Joseph A Jerger M D, the statement is made that "Once every lump in the breast was considered either cancer or potential cancer and all the breast removed. Now we can test the lump for malignancy by taking out a small piece with a hollow needle. May I ask if this technique is used in the large medical centers and if it is simple enough to be used in small hospitals without a pathologist?"

Evo Cutright M D Wooster Ohio

ANSWER—The removal of tissue from suspected cancer of the breast by means of a needle is not universally employed in the large medical centers. This method is useful under certain circumstances. It requires considerable skill and experience particularly in the interpretation of such small specimens. The interpretation of borderline or precancerous lesions by this method is accompanied by considerable hazard. The accepted and safest method to use is removal of the tumor or a portion of it with the knife and the microscopic examination of the frozen section.

PERIADENITIS MUCOSA NECROTICA RECURRENS
OR LICHEN PLANUS

To the Editor—In The Journal of July 11, 1942 in a query from Dr. M. E. Friedman of New Buffalo Mich. entitled "Periadenitis Mucosa Necrotica Recurrens" he states that examination reveals linear white elevations along the inner sides of both cheeks. The patient also has a history of having had lichen planus about a year ago. Nearly any dermatologist hearing this description immediately thinks of lichen planus. This disease occurring on mucous membranes is one of the most resistant to treatment with which we deal. Furthermore the disease tends to recur. The diagnosis of periadenitis mucosa necrotica recurrens is based entirely on the patient's history and is a much less common condition than lichen planus of the mouth. Some authorities believe the latter disease is never cured but surely a trial of mercury or arsenic ingestion is warranted in the form either of mercury with chalk or of solution of potassium arsenite. Injection of bismarsen has also been highly recommended by the St. Louis group recently. Certainly the most likely diagnosis in Dr. Friedman's case is lichen planus of the mouth and a careful search of the patient's body should be made for lichen planus especially on the flexor surfaces of the extremities. The patient's history may have been misleading or she may even have some mucous retention cysts that recur as well as lichen planus.

Roy L Kile M D Wichita Falls Texas

TYPHOID VACCINE FOR HYPERTYREXIA

To the Editor—Queries and Minor Notes in The Journal Aug 22 1942 contains a question on the use of triple typhoid vaccine intravenously. One of the reasons why many have been disappointed in the use of triple typhoid vaccine as a means of producing hyperpyrexia has been the difficulty of obtaining prolonged sustained controllable temperature elevations. Another has been the risk of serious reactions. In a recent article Dr. Somkin and I have described a method of obtaining hyperpyrexia with triple typhoid vaccine by suspending the organisms in saline solution and administering them in a continuous intravenous infusion. By this means we have obtained repeatedly temperatures of over 104 F for four to eight hours. Considering the extremely slow delivery of the organisms as compared with the single injection technique and the fact that it calls for a nurse in constant attendance we believe that the element of risk is greatly reduced. Used in combination with the sulfonamides the scope of fever therapy has been broadened to include diseases which formerly gave poor therapeutic results. Surely the danger involved is small compared with the therapeutic possibilities, particularly when the chief element contributing to the risk is the disease process itself. Using this method I have used fever therapy in severe congestive heart failure uremia (chronic glomerulonephritis associated with chronic dermatitis) and periarthritis nodosa. One is usually amazed at how well such patients stand hyperthermia and the results are frequently gratifying. Harry A Solomon M D New York

SUBTOTAL GASTRECTOMY FOR STENOSING DUODENAL ULCER

CHAIRMAN'S ADDRESS

ARTHUR W ALLEN, M D

Chief East Surgical Service Massachusetts General Hospital
Lecturer in Surgery Harvard Medical School
BOSTON

When duodenal ulcer becomes a surgical problem, it can be classified roughly into four categories. These are acute perforation, massive hemorrhage, intractability and cicatricial occlusion. Although I wish to emphasize in this discourse the more careful consideration of stenosing ulcer of the duodenum, it is difficult to avoid a brief summary of the other complications of duodenal ulcer. This is done to call attention again to the importance of the problem as a whole and to avoid misconception regarding the treatment of a relatively small percentage of all patients who are afflicted with this lesion.

ACUTE PERFORATION

There is little dispute regarding the advisability of early operation and simple closure in the first group. The earlier the closure is done, the lesser the risk, provided the perforation is under twelve hours' duration. If delay has inadvertently passed this time limit, one may do well to evaluate the question of spontaneous sealing and further conservative measures.¹

In some communities the mortality is higher than it is in others, as the result of an older age group affected, delay in hospitalization and the virulence of the current respiratory tract infection. In a series of cases analyzed by Ulfelder and Allen,² perforation, closed within three hours, was found to carry a mortality rate of approximately 5 per cent, while in those in which operation was done during the second three hour period the mortality rose to 18 per cent. Radical operations for acute perforation, in our opinion, are contraindicated.

MASSIVE HEMORRHAGE

I have reported on acute massive hemorrhage associated with duodenal ulcer and feel that, in our own geographic locality, we can expect certain rules to apply.³ It is obvious that the experience in some com-

munities is similar to ours, while in other areas the prognosis is better than it is with us. In the vicinity of Boston we find that approximately 9 per cent of all duodenal ulcer patients coming to the Massachusetts General Hospital have massive, acute bleeding. Thirteen per cent of these die of acute anemia, if treated conservatively, even if more modern methods of early feeding and so on are used. Thus the complication of hemorrhage can account for 13 per cent mortality in all duodenal ulcer patients treated in one clinic. The summary of our data reveals that nearly all the patients under the age of 45 will spontaneously recover from acute bleeding, while approximately 30 per cent of those above this age will succumb. This variation, we believe, is largely due to the inability of an arteriosclerotic vessel to contract sufficiently to hold in place a thrombus over a long enough period of time. We have further shown that operation, undertaken in this older age group after a week or more of repeated bursts of bleeding, will nearly always fail. On the other hand, if operation is carried out within seventy-two hours of the onset of bleeding, success is likely. Actually, in 6 instances in my own group, all of those bleeding massively for more than seven days at time of operation died, with one exception. Of 9 patients operated on within seventy-two hours of onset, 8 recovered. All of these were in or beyond the fifth decade of life. The last patient in this group was 77 years of age.

It is obvious to us that the younger patient should be allowed to regain an optimum state of health and then be subjected to radical cure. The older patient should be carefully evaluated, the diagnosis established by immediate fluoroscopy if necessary and the decision made for or against surgical treatment within seventy-two hours of onset. If conservative treatment is elected for one reason or another, one should not be persuaded to attempt a late rescue. I have seen a few of these patients recover spontaneously after a time when death seemed certain, and these more than offset the chance of surgical success after several days of severe bleeding.

INTRACTABILITY

The term intractability is difficult to define. We use it to cover a group of recalcitrant ulcer patients who for one reason or another cannot get along on conservative measures. Approximately 5 per cent of duodenal ulcer cases treated in our clinic fall into this group. I have included in this category ulcers deeply penetrating the pancreas, those interfering with the proper function of the biliary tract and those that involve the pyloric sphincter. These locations make it difficult for the patient to remain symptom free except on a strict hospital regimen. Also there are economic factors that enter into the picture in some of these individuals to

such an extent that quiescence of the ulcer is incompatible with work. Some of them may be aided by the psychiatrist, while others are actually not willing to help themselves or do not possess the intellect to carry on their job and take care of their malady. The surgeon should review with great care any patient referred to

Fig. 1—Typical stenosing duodenal ulcer, old adhesions not interfering, with ideal operation.

him with so-called intractable ulcer. He will often be confronted with the burden of the entire treatment and will find less cooperation on the part of his patient than he is accustomed to in dealing with the average surgical problem. It is in this group that we are really on trial as to the outcome of our endeavors, and it is from these patients that we can expect the highest percentage of failures. I am sure that if we have learned to relieve the majority of such individuals by surgical methods they have taught us much regarding our present conception of the proper operative procedures to carry out for the relief of duodenal ulcer.

STENOSING DUODENAL ULCER

Either because of repeated activity with extension in a circular direction or because of the development of multiple ulcerations on opposite walls of the duodenum, there comes about a constriction from scar tissue in a certain proportion of ulcer patients. Although such cicatricial occlusion to the outlet of the stomach is occasionally encountered in the young adult, it is more often found in those past middle life. There is in either case a prolonged ulcer story with almost constant or recurrent signs of activity, requiring some attention on the part of the victim to more rigid efforts directed toward the relief of symptoms. This finally becomes a mechanical problem and the patient seeks help because he can no longer absorb enough nourishment to maintain life. The onset of such a condition is a gradual one, and the end stage is reached so insidiously that one often finds that the stomach has become enormously dilated. It is interesting that such an organ, emptying infinitesimal amounts of its contents into the duodenum, can exist within a person and create so little distress. Many of these patients have found that emptying their stomachs by tube or induced vomiting once in twenty-four hours gives them a few hours of respite. A considerable number of them are disturbed only by weight loss and gaseous eructations.

On investigation, one often finds the enlarged stomach clearly outlined in an otherwise scaphoid abdomen. Barium sulfate, when introduced, may appear not to leave the stomach during the fluoroscopic examination, and a large residue is noted after twenty-four hours. The roentgenologist has little difficulty in arriving at the obvious diagnosis of pyloric obstruction and has become proficient in the differential diagnosis between obstruction due to old duodenal ulcer and malignancy of the prepyloric region. The gastric secretions in such cases will show a low or subnormal acidity. This is believed by some⁴ to be due to the effect on the acid cells of gastritis secondary to prolonged obstruction.

Such lesions have been thought to be the end result of healed duodenal ulcer, and I among others have felt that one need do no more than correct the mechanical situation. That this was considered sufficient was based on the opinion that without recent activity in the ulcer and with the low acid findings one could expect a good result from some short circuit or pyloroplasty type of operation. The immediate results from such procedures in this group have been good and, in many instances, appear to continue satisfactory. Although we believe there are a greater percentage of cures in this type of ulcer patient by palliative surgery than in any other except those with acute perforation, the question regarding the kind of operation to be done for them should be reviewed.

In my personal cases there have occurred 3 jejunal ulcers following posterior gastroenterostomy for cicatricial obstruction. Two of these were in elderly men, who obtained relief by gastroenterostomy for several years. Having lived on an ulcer regimen off and on for a greater part of their lives it was easy in well established households to continue a reasonable existence after operation. In each instance after the death of the patient's wife ulcer symptoms returned, doubtless as the result more of the abandonment of a proper

Fig. 2—Exposure of region of common bile duct by turning the duodenum fully, assuring adequate amount of uninvolved duodenum below the ulcer site.

ulcer regimen than of the natural results of grief. One of these patients had the jejunal ulcer at the age of 82 and it was responsible for a sublethal acute massive hemorrhage. The reestablishment of a sensible mode of living gave him a fairly happy additional two and

⁴ Ochsner, Alton, Gage, Mims and Hosoi, Kiyoshi. Treatment of Peptic Ulcer Based on Physiological Principles. Surg. Gynec. & Obst. 62: 257-274 (Feb. number 2A) 1936.

a half years. When the other patient was told of his situation he applied elsewhere for treatment and has, I believe, continued on conservative measures.

More recently a man aged 47 was admitted to the medical wards of the Massachusetts General Hospital with a typical stenosing ulcer of the duodenum. He

Fig 3—Ideal operation completed consisting in subtotal gastrectomy including first portion of duodenum.

had survived the suture of an acute perforation twelve years previously and had continued since that time with periods of ulcer activity. He was treated conservatively for seventeen days without improvement of the obstruction. His fluid and chemical balance were restored and he was transferred to the surgical wards. During his hospital stay his nonprotein nitrogen remained high and he continued to show albumin and casts in his urine. Gastric analysis revealed 38 units of free acid after histamine. It was felt that he was a poor surgical risk, and posterior gastroenterostomy was performed. He made an uneventful recovery and there was a rapid fall to normal level of his nonprotein nitrogen. He was discharged home on the fourteenth postoperative day greatly improved but was readmitted through the emergency ward seventy-seven days after his gastroenterostomy with all the signs and symptoms of acute perforation.

Operation at this time revealed the perforation to be a large one in a jejunal ulcer opposite the anastomosis. Recovery from the closure of this acute perforation was uncomplicated save for the fact that tenderness and ulcer type of pain persisted. Consequently a third operation consisting of subtotal gastrectomy was done eighteen weeks after the first and six weeks after the second operation. At this time the patient was in better physical condition than at his first procedure but, considering the necessary extent of the final operation, the prolonged disability and the narrow escape from death following the acute perforation, we are convinced that better judgment could have been used in the first place. His recovery was uneventful following his last operation and he was discharged home on the fifteenth postoperative day. So far he has remained symptom free, having returned to light work two months after discharge. He has gained 6 pounds (2.7 Kg) in weight in the past eight weeks, this gain becoming evident about three months after operation.

I am sure that before we subject patients with cicatricial obstruction subsequent to duodenal ulcer to operation we should seriously consider more radical surgery than we have formerly advocated. In the past five years we have subjected several such patients to subtotal gastrectomy and have been agreeably surprised to find that in such cases the operation is technically made easier by the nature of the process. The large stomach is easily handled, and the lack of acute inflammation about the ulcer site enhances a safe resection into healthy duodenum. We have at times prepared these patients for gastrectomy by preliminary jejunostomy for feeding. More recently, however, we have depended on artificial methods for the restoration of fluid and chemical balance and followed the resection with concomitant jejunostomy so that there would be little delay in utilizing the gastrointestinal tract. These patients have done well and, in accordance with our past experience with postoperative ulcer cases, we are sure that they are as nearly immune from further ulcer trouble as it is possible to make them in the light of our present knowledge of this lesion.

One may inquire into the acidity in this group and rightly wonder why activity should return after palliative operations. It is difficult to obtain dependable analysis of the stomach contents in the presence of a gastroenterostomy. Attempts have been made by many observers, and some by persistent effort seem to have shown that the acid level is at times high under these circumstances. Although difficult to prove, I believe that the decompression accompanying gastroenterostomy or pyloroplasty in these cases allows the acid cells

Fig 4—Modification of subtotal gastrectomy for exclusion. The antral mucosa has been removed before closure of the distal stump. This operation is applicable when ulceration and inflammatory reaction are extensive.

to regain their former activity. This being the case, if true, it is not surprising that the complication of jejunal ulcer occurs, since the patient has an ulcer diathesis and returns to his former vulnerability with the elimination of his obstruction.

It seems now that there is a consensus among most surgeons regarding the need of subtotal gastrectomy for the relief of the ulcer patient who cannot be kept

well on conservative measures. I believe we should apply the same principle to patients with cicatricial stenosis from duodenal ulcer. If palliative operations are done in this group, one must be prepared for failure. Certainly no patient in reasonable condition or with a normal life expectancy should be subjected to an inadequate procedure.

I wish to call attention to the differential diagnosis between the type of scar tissue stenosis just discussed and the edematous obstruction frequently seen in the acute exacerbation of duodenal ulcer. In the former group the condition is insidious in onset, and in most of the cases a long history of ulcer symptoms is obtained. In this group the obstruction fails to respond to conservative measures. In those with edematous occlusion the onset is rapid and coincident with an obvious return of symptoms compatible with ulcer activity. These individuals are of a younger average age, and on decompression with a Levine tube and supportive measures the edema subsides within a period of ten to fourteen days. Treatment after the acute episode has passed is dependent on the usual factors governing duodenal ulcer management in general. Many such patients have not had a fair trial on a conservative regimen and should not be subjected to radical surgery until it is obvious that for one reason or another it is justifiable.

Subtotal gastrectomy for duodenal ulcer, as the procedure of choice for the relief of the small group of ulcer patients who fail to respond to conservative management has come about by the trial and error method. Even conceivable less extensive operation has been advocated in the past. Owing to the poor selection of cases requiring surgery in the earlier years of our experience, the results obtained have been difficult to evaluate. Conservative operations applied to the group that we now believe require surgery for cure are associated with such a high percentage of failures that we are convinced of the rationale of a radical operation when any is done. This, in my opinion, means the removal of not less than one half of the distal stomach including the antrum and the pylorus.⁵

Connell⁶ believes that good results can be obtained by an extensive fundusectomy, thus eliminating a large proportion of the acid cells. We have had no experience with fundusectomy per se but believe that we have accomplished the elimination of a similar amount of the acid cell area in many of our subtotal resections for exclusion. In this group, if the antral mucosa was left in situ the incidence of anastomatic ulcer was higher than in any of the other conservative operations in our cases. This experience makes us feel that the antrum must be eliminated entirely if one wishes to be sure of the end result.

After subtotal resection it is often apparent on examining the specimen that antral cells extend much farther into the mid-stomach than is normally expected. In fact, it is not uncommon in a chronically dilated stomach to find smooth mucosa without rugae a distance of 10 to 12 cm proximal to the pylorus. Since some of the surgeons in our own institution have resected a

smaller segment of stomach than others, we have been able to compare the results according to the extent of the operation. It was found that the results were good in all patients who had had the distal half or more of their stomach removed. Those having pylorotomy or partial gastrectomy of less than one half gave a high incidence of good results, but some of them had continued symptoms, usually based on anastomatic ulcer. We believe that the discrepancy in results in the less extensive resections may well be due to the anatomic variation in the extent of antral cells in different patients operated on for ulcer.

The ideal operation at the moment seems to me to consist in a resection of from one half to two thirds of the distal stomach, including the antrum, pylorus and ulcer bearing portion of the duodenum. This can be carried out in the stenosing ulcer group more regularly than in any other, although in most of the patients operated on for intractability or massive hemorrhage we have been able to accomplish the same procedure. The complications of present day gastric resection for ulcer are nearly all based on the difficulty in the management of the duodenum. In a series of sixty five consecutive gastric resections for uncomplicated gastric ulcer at the Massachusetts General Hospital, there has been only one death. During the same interval of time a larger number of duodenal ulcer patients have been operated on by the same group of surgeons with a mortality rate of about 5 per cent. This variation is largely due to the complications arising from the duodenal segment during and subsequent to the operation.

If a patient with duodenal ulcer must be subjected to operation for one reason or another, it is wise to have at our disposal a variety of maneuvers. We feel that gastroenterostomy or pyloroplasty should be used rarely, since the ultimate outcome so often proves unsatisfactory. Subtotal resection for exclusion as advocated by Finsterer⁷ is not followed by any better results than the less radical palliative operations. If the antral mucosa is removed from the remaining distal segment, as originally advocated by Finsterer, then the results in a comparable group of our own cases have proved satisfactory. We use this modification of the ideal procedure with some reluctance, since we have found that the antrum is a thin friable structure after its mucosa is eliminated and offers, under these circumstances tissue that may not lend itself to suitable closure.

One may in difficult cases deliberately plan a two stage resection as advocated by McKittrick.⁸ This consists in the Finsterer exclusion subtotal gastrectomy as the first stage, leaving the antrum and ulcer area in the duodenum intact and undisturbed. The second stage comprises the relatively simple procedure of removing the antral segment and first portion of the duodenum six weeks later. Although this two stage operation will be found necessary in a relatively small number of cases, it has without doubt a definite place in the role of sound surgical judgment in the treatment of duodenal ulcer.

In the average patient, who has had suitable preparation, one can usually accomplish an ideal resection with little difficulty and with a low mortality rate. It is wise to continue preoperative preparation as long as the patient improves and until acute reaction about the ulcer site has subsided. When it is decided that an ulcer patient had best submit to radical operation, the surgeon should delay his part in the program until he feels that the circumstances are best for a happy outcome. Although this may mean waiting no longer than it takes to combat shock from massive hemorrhage, it more often means waiting several weeks for an acute ulcer to subside and for the patient to regain the body tone lost by bed rest. Often the patient may be given a better chance by a two weeks ambulatory period before the operation is undertaken.

At the time of operation the surgeon must decide the procedure best suited in that particular case. The extent of the reaction about the ulcer site, the condition of the patient at that time and other technical hazards must be weighed. One may without harm free the lateral border of the duodenum and determine the course of the common bile duct without disturbing the protective adhesions about a penetrating ulcer. Often one finds the duodenum foreshortened and drawn into the liver sulcus, and this should not be tampered with until a decision has been reached that there remains a sufficient amount of normal duodenum between the ulcer and the pylorus of Vater to allow an adequate closure of the duodenal stump. If on inspection it is found that the inflammatory reaction involves too much of this area for comfort, one should immediately resort to one form or another of the exclusion operation. Occasionally one finds that there is sufficient duodenum beyond the pylorus but proximal to the ulcer for adequate closure. This circumstance is, in our opinion, one that can be safely met by leaving the ulcer in situ since with the duodenum adequately closed above it the ultimate result will be satisfactory.

TECHNIC

The technic of operation for subtotal gastrectomy for duodenal ulcer is varied by different surgeons. Some begin by freeing the duodenum and closing the remaining duodenal segment. I have seen this skilfully done by several men. Often, however, the difficult part of the operation is easier for me if I approach it from the other direction. For this reason I have routinely freed the gastric segment and transected it prior to the dissection in the region of the ulcer. This method allows a free exposure of all sides of the inflammatory area and makes it possible to remove this segment under direct vision. In my own hands I feel that there is better control of the situation when this is done. One can easily avoid undue injury to the adherent pancreas and keep in view the bile ducts and other structures in this area with more assurance. If one elects to free the stomach segment first, it is made easier for the operator if he stands on the left side of the patient. By freeing the greater curvature in the beginning, one can, by placing the left hand behind the stomach, control the left gastric vessels on the lesser curvature with greater facility.

I have found fine chromicized catgut on atraumatic needles satisfactory for the suture lines. Great care

is used to infold all mucosa, since healing of these structures takes place only from the serous layer. Thus, a loose but firm approximation of the outer surface of these segments is desirable. If one keeps this in mind, along with adequate control of bleeding, healing will take place quickly and hemorrhage from the cut surfaces will be insignificant.

There is much discussion at the moment regarding anterior or posterior anastomosis following subtotal gastrectomy. In our hospital during the year of 1941 there were forty-nine subtotal gastrectomies for ulcer. About two thirds have had posterior and one third anterior anastomosis. All have done equally well as far as immediate convalescence is concerned. We prefer the short loop posterior hookup in the virgin case with a normal mesocolon that is not thickened by fat deposit. In obese persons and those who have had previous posterior anastomosis we prefer anticolonic gastrojejunostomy. In many of those having had anterior anastomosis we have noted troublesome regurgitation of bile from the long proximal segment when the patient reclines at the end of the day during convalescence. This complication is not of great importance and usually subsides after a few weeks. Under no circumstances should one be tempted to relieve this situation in ulcer patients by enteroenterostomy between the jejunal loops, since this will result in anastomotic ulcer in a large percentage of cases.¹⁰

If one allows the stomach segment to become acutely distended, it will take some time for its tone to return, and this, added to the usual early lack of peristaltic activity in the remaining stomach, delays convalescence. In patients who must be subjected to surgery at a minimum level of safety, as regards blood chemistry and nutrition, it is wise to provide concomitant jejunostomy for feeding.¹¹ If this has been omitted at the original operation and the stoma fails to function for seven days after operation, then jejunostomy for feeding should be done. This procedure will allow easy restoration of fluid and chemical balance, which is not only life saving but enhances the proper functioning of the anastomosis.¹²

Patients who have long been disabled, periodically or continuously from duodenal ulcer, will soon regain self confidence after radical surgery. It requires three to twelve months for some of these persons to acquire an appetite and begin to gain weight. The majority can carry on their usual occupation after three months' convalescence and live comfortably on three regular meals a day. For a time, many of them find it best to eat smaller meals more frequently but seldom is it necessary to carry this out indefinitely. All are discharged on a six meal bland diet and are given instructions regarding abstinence from highly seasoned foods, alcohol and tobacco. Many of them find that these restrictions are unnecessary. Although our early follow-up results, three to nine years, would indicate that recurrent ulcer is an unusual occurrence, we still feel that these people should regard their apparent good health with gratitude but without complacency.

MANAGEMENT OF SKULL FRACTURES
AND BRAIN INJURIES

HARRY E MOCK, MD
AND
HARRY E MOCK JR, MD
CHICAGO

For the last twelve years the senior author has made a hobby of collecting consecutive proved skull fracture records from all sections of the country as a means of securing a cross section of management of brain injury cases by the profession. This paper is based on the accumulated material from 7,031 consecutive proved or practically proved skull fracture-brain injury cases. In addition to the 487 cases that we ourselves have treated or seen in consultation we have collected 6,544 consecutive skull fracture cases covering the period 1928 to 1940 from approximately one hundred surgeons and fifty hospitals representing every section of the country. This report is dedicated to these surgeons and the medical staffs of these hospitals, whose unselfish cooperation has made this clinical investigation possible.

Facts collected from various sources warrant a conservative estimate of 600,000 serious head injuries, one

deaths occurred in the first six hours following the injury. In the consecutive cases surveyed from nineteen hospitals 47 to 56 per cent of their total deaths were likewise first day fatalities. Thus it is evident that the type of management rendered during the first twenty-four hours, and especially during the first six hours, spells life or death for many of these victims.

Given the wide distribution and the high preponderance of deaths in the first twenty-four hours, it is axiomatic that

A A large proportion of brain injuries must be treated in hospitals far removed from the centers where neurosurgeons work.

B The full responsibility for reducing the mortality rate in the majority of instances rests on the shoulders of the general physicians and surgeons who first see these cases.

"SKULL FRACTURES" VS "HEAD INJURIES"

Injuries to any one or all of the three intracranial elements are grouped under the general heading "brain injuries." Not all head injuries are brain injuries. Very few skull fractures occur without some brain injury. The presence and extent of brain injury determine the management and outcome of the case.

Wright and his co-workers¹ reported 349 craniocerebral injuries in 1933. Twenty-five per cent of these were skull fractures. The mortality rate for the entire series was 17.7 per cent. Fay² in 1935 reported 655 cases, 30 per cent skull fractures and the remainder showing blood in the spinal fluid thus indicating comparable seriousness. The mortality rate for his series was 17.8 per cent. Swift and Berens³ in 1938 reporting 1,747 personal and collected cases 7 and 15 per cent skull fractures, showed mortality rates of 11.7 and 13 per cent. Mock⁴ in 1939 showed a 5 per cent reduction in his skull fracture mortality rate by including an equal number of serious head injuries.

In order to secure uniformity of statistics in this comparative study of management only proved and practically proved skull fractures have been used.

CONTROVERSIES CONCERNING MANAGEMENT

No chapter in surgery is so filled with controversy as the one dealing with the management of acute craniocerebral injuries. Briefly, these controversies during the first forty years of the present century can be summarized as shown in table 2. The literature on management of brain injuries for the last five years indicates greater unanimity concerning certain major life saving procedures than was true for the preceding thirty five years of this century. However, confusion still exists in the minds of many surgeons regarding the treatment of their occasional cases. The chief dilemmas concern the value of dehydration, whether or not to do a lumbar puncture and when if ever operation is indicated.

There must be a rationale for these procedures which the majority seem to favor and only the few condemn. The Monroe-Kellie doctrine, enunciated one hundred years ago, stands as the very foundation of our modern conception of brain injury therapy. This doctrine stated that the total contents of the noncompressible cranium must be approximately equal at all times, but vary

TABLE 1—Source of 7,031 Consecutive Cases of Proved Skull Fracture Collected

third of them proved skull fractures, as the annual incidence of this type of trauma. With average mortality rates of 10 per cent for serious head injuries without skull fractures and an average death rate of 30 per cent for proved skull fractures it becomes apparent that 100,000 of our friends, neighbors and relatives are being killed—nearly 300 people each day—by brain injuries. Such a death rate from any one given type of trauma is a challenge to the surgeons of the land worthy of their greatest effort.

SOURCE OF SKULL FRACTURE CASES

The source of the 7,031 skull fracture cases included in this clinical investigation is shown in table 1. The causal agency for each case of skull fracture collected furthermore furnishes a cross section of the nation as regards the chief etiologic factors. Motor driven vehicles were responsible for 50 per cent of these skull fractures, falls for 26.8 per cent and blows for 10.3 per cent. Miscellaneous or unknown causes made up the remaining 13 per cent. Such potential etiologic factors are scattered all over the land. Every hamlet, village and city has its quota of craniocerebral injuries.

Moreover, the majority of deaths from skull fractures and brain injuries occur in the first twenty-four hours, depending on the efficacy of the management. In the authors' series of cases death occurred in 64 per cent of the total number of fatal cases within the first twenty-four hours and 60 per cent of these first day

Owing to lack of space this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints. Read before the Section on Surgery, General and Abdominal at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

tions in volume of any part of these contents, consisting of the three elements brain blood and cerebrospinal fluid may occur at times—a decrease or increase in the volume of any one of the three elements is immediately compensated for by reciprocal alterations in the volume of one or both of the remaining elements. Quincke⁵ in 1902 showed that one of these component volumes, the cerebrospinal fluid, could be reduced by drainage of this fluid through a spinal puncture performed in the lumbar region. Weed and his co-workers⁶ in 1921 discovered the ability of hypertonic solutions injected intravenously to reduce not only the edema of tissues but the amount of cerebrospinal fluid. These doctrines have resulted in two valuable therapeutic measures, namely dehydration and spinal fluid drainage. Both measures have played a major part in reducing brain injury mortality rates.

Dehydration—The chief criticisms aimed at this method of therapy deal with the dangers of overdehydration, the deleterious effects on the kidneys by the prolonged use of hypertonic salt and sucrose and the tendency to cause a reverse osmosis especially with dextrose. The ability of hypertonic solutions to withdraw fluid from the body tissues into the blood vessels, thence to be eliminated through the kidneys or bowel has been proved both scientifically and clinically. When combined with limitation of fluids, the fluid reservoirs of the body may be completely evacuated. Fatalities occur from such excessive dehydration. All these criticisms are valid, but they do not hold water when a careful adequate plan of dehydration is followed only when and if indicated.

Lumbar Puncture—The authorities writing on craniocerebral injuries during the third decade of this century were divided into two camps: those who favored and those who opposed lumbar puncture. The latter warned the profession against the danger of herniation of the medulla through the foramen magnum—a danger so frequently noted in the presence of brain tumor. Those who favored the procedure advocated spinal punctures as a far safer method of management than the old subtemporal decompression operation. Some of these believed in routine spinal puncture of every patient with head injury admitted to the hospital whether unconscious or otherwise. Others believed only in diagnostic lumbar puncture, chiefly to ascertain the spinal fluid pressure or the presence of a subarachnoidal hemorrhage. Some favored draining only a sufficient amount of fluid to bring the manometer reading to normal or slightly above, thus often removing only 5 or 10 cc or only 1 cc if no increased pressure was present. Others, notably Temple Fay, advocated "complete drainage," pointing out that this was the only element of the three component volumes that could be removed. The senior author⁷ in his 1931 publication condemned all routine measures and stressed the need of individualizing the treatment. He believed then and has continued to teach that, when the signs and symptoms indicated the need, spinal drainage with removal of 30 to 60 cc of fluid, if performed early, was life saving. In his experience these indications were present in 33⅓ per cent of all proved skull fractures.

Because a few outstanding authorities still condemn spinal drainage, many a general physician and surgeon still fears the procedure. To these we recommend the article written by Rowlette and Weiner⁸ in 1941—an article which should convince any surgeon of the value of dehydration and spinal drainage. They give a comparison of the mortality rates in two services at the St. Louis City Hospital. Prior to 1938 all patients with brain injury were treated with a very limited type of dehydration and seldom received a lumbar puncture. A survey of all skull fractures and truly serious head injuries treated from 1934 to 1937 revealed a mortality rate of 38.9 per cent. In 1938 two units were established in the St. Louis City Hospital for the treatment of proved brain injuries. Each unit received every other case in rotation. Unit A continued to treat the skull fracture-brain injury case by no limitation of fluid, a very moderate dehydration and only an occasional spinal puncture. Unit B adopted the most radical dehydration for forty-eight hours and almost routine early lumbar puncture and, when indicated, frequent repeated punctures, with practically total drainage of all the spinal fluid at each tap. The mortality rate for unit A was 37.3 per cent. The mortality rate for unit B was 21

TABLE 2—Major Controversies Concerning Treatment of Craniocerebral Injuries Since 1900

1900-1910	Trephining vs nonoperative treatment
1910-1920	Subtemporal decompression vs spinal puncture vs do nothing treatment
1920-1930	Routine spinal puncture vs never do a spinal puncture vs dehydration treatment
1930-1940	Spinal drainage when indicated vs routine vs no spinal puncture Radical vs mild vs no dehydration Subtemporal decompressions (10% Dandy) vs exploratory decompressions (67% Munro) vs delayed operations for certain definite lesions

per cent. For the years 1939 and 1940 the combined mortality rate for the two services was 28.5 per cent as compared with the previous high rate of 38.9 per cent.

Subtemporal Decompression—This procedure was advocated by Cushing⁹ in 1908 for "bursting fracture of the skull." During the decade following his publication the operative rate in skull fractures and brain injuries jumped from 12 per cent to 25 per cent, as indicated by a review of the literature. The originator of this operation ceased doing it except in very selected cases many years prior to his death. In personal correspondence he advocated lumbar puncture as a safer procedure, except in certain instances, when conservative methods proved ineffective. Few of the neurosurgeons writing on this subject of acute brain injuries during the last five years approve this operation. The pendulum swinging from the high operative rates of a decade or more ago has swung so far toward conservatism that many a needed operation today is neglected or delayed too long.

Exploratory Decompression—This has replaced subtemporal decompression almost completely. Munro,¹⁰ one of the strongest advocates of exploration, stresses the frequency of undiagnosed subdural hemorrhage in head injuries. His operative rate in 1,203 cases was 36.9 per cent. Many of these were undoubtedly late

cases, the operation being done by a great specialist. Such a high operative rate should not be advocated at the average physician and surgeon treating the acute case.

MANAGEMENT JUDGED BY MORTALITY RATES

Two nationwide surveys of proved or practically proved skull fractures have been made by the senior author covering the years 1928 to 1940. The first survey included the consecutive skull fracture records submitted by approximately one hundred surgeons on a prepared survey sheet and included cases treated from 1928 to 1935. Prior to 1935 the author, assisted by

TABLE 3—Survey of 6262 Consecutive Cases of Proved Skull Fracture

Years	Total Number of Cases	Total Deaths	Range of Death Rates	Average Mortality
1928-1935	3,156	1,098	25 to 49%	35%
1935-1940	3,106	896	17 to 42%	29%
Totals	6,262	1,994		
Average improvement in death rate				7%

Drs. A. R. Morrow and Charles E. Shannon, surveyed the consecutive skull fracture records for a period of five years in ten hospitals in and adjacent to Chicago. In addition, certain surgeons copied pertinent facts on his survey sheet covering the consecutive five year records in eight other hospitals located in various sections of the country. Thus, the first survey includes the studies of 3,156 consecutive skull fracture records.

The second nationwide survey was started in 1940 in an effort to answer the challenge tossed to the senior author by Dr. Louis Pollock: "Can you prove that dehydration and spinal drainage have played a part in reducing the high mortality rate from brain injuries?" Although an arduous task, this clinical investigation has repaid us and those surgeons participating in it a hundred fold. Drs. John Lindquist, S. R. Snead and F. E. Sarver surveyed the consecutive records from 1935 to 1940 in twelve hospitals, with the consent of their staffs, in Illinois, Wisconsin and Indiana. In addition, certain surgeons filled in our survey sheets from the records of twenty-six other hospitals representing every section of the country. The junior author has assisted in tabulating the accumulated material. The cases from two or three hospitals in medium size cities are combined as though from one hospital. Thus the second nationwide survey covers the 3,106 consecutive records for this period of five years in nineteen hospitals labeled A to S. Table 3 shows the total number of cases studied in each survey and the results of management as gaged by the mortality rates. The improvement in results is encouraging. The duty placed on the junior author is to repeat this nationwide survey in ten years. May he find better and more uniform results as judged by mortality rates.

Standards of observation and of good, average and poor treatment were established in order to compare the management and results thereof among the 3,106 collected cases of this second survey. Each individual case record from each hospital was graded according to these standards. The average of the grades for the total series of cases in each hospital determined the management group to which the hospitals belonged. Table 4 shows the points on which each management group was graded. The mortality rate found in each group justified these grades.

Further analysis of these nineteen hospitals that treated 3,106 consecutive skull fractures during a five

year period revealed that these skull fractures were of equal seriousness judged by the relative proportion of linear, basal and combined fractures. The staffs of four of these hospitals so managed 323 cases that the mortality rates ranged from 17 to 21 per cent. The staffs of five so managed 2,033 cases that the mortality rates were 23 to 29 per cent. But the staffs of ten hospitals rendered such poor management in 750 cases that death rates mounted to 30 to 42 per cent. Why this wide divergence in results?

OBSERVATION

If in every case of severe craniocerebral injury one could lift the cranial cap and actually visualize the pathologic changes in the brain and in its blood and cerebrospinal fluid circulations, the management of the case would be simplified and many controversial problems concerning treatment would be solved immediately. But the surgeon viewing the unconscious patient with a severe head injury must depend on the signs and symptoms, rarely stationary, more often showing changes in variety and intensity, if he is to approach even an approximate diagnosis of the pathologic changes inside that skull.

The changeability of the signs and symptoms and the importance of recognizing and interpreting many of these changes is the strongest argument for close observation and charting the course.

The value of close observation is reflected in the mortality rates of the good, average and poor management groups in table 4. The good management group, with a grade of 85 per cent for observation, means that with few exceptions every case record had the blood pressure, pulse, respiration and temperature charted at least every two hours and many as often as every thirty minutes. This "charting of the course" indicates that these surgeons were in control of their cases at all times. The observation grade of 54 per cent in the poor management group represents a far different situation—blood pressure often neglected and pulse, respiration and temperature charted only two or three times a day. Such charting indicates poor navigation.

TABLE 4—Good, Average and Poor Management Graded on the Following Points

Hospitals Grouped According to Management	Good A to D	Average E to I	Poor J to S
Number of consecutive skull fractures	373	2,033	360
Mortality rates	17 to 21%	23 to 29%	30 to 42%
Observation average grade	85%	73%	54%
Treatment average grade	82%	69%	45%
Shock rules observed	85%	70%	38%
Dehydration when used was adequate	90%	70%	38%
Spinal tap when indicated was done early (first 24 hours)	78%	50%	40%
Spinal fluid drainage sufficient (20 to 70 cc)	80%	45%	18%
Operative judgment good	78%	80%	50%

TREATMENT DURING THE FIRST SIX HOURS

Cerebral shock causes many of the early deaths. Grafted on the condition of ordinary traumatic shock are the manifestations of direct or indirect damage to the vital cerebral centers, thus presenting a definite entity—cerebral shock. Disturbed consciousness, varying from a dazed condition to deep coma, usually accompanies this form of shock. In addition to the ordinary signs of shock, the slowed pulse, slow, shallow respirations and low blood pressure, especially a low diastolic pressure, indicate the presence of cerebral shock. The signs and symptoms of the cerebral damage may overshadow the shock picture from the onset.

Thus a few patients pass rapidly from delirium to the deepest coma, the respirations increase rapidly or change to a Cheyne-Stokes variety, the pulse pressure becomes considerably increased and the temperature jumps rapidly from 100 to 106 F or more. Death may occur within a few minutes to a few hours. These patients present the picture of inevitable death and do die if "do nothing treatment" is followed, yet certain ones of these may be saved by proper management. In the majority of cases the shock picture predominates for the first one or two hours, when it slowly changes into the picture of cerebral damage. When severe associated injuries are present the shock combined with the cerebral manifestations is often very profound. The wise surgeon will treat every head injury patient the first one or two hours after admission as one having potential cerebral shock regardless of associated injuries, except the 1 or 2 per cent who may have life threatening hemorrhages. The tendency to minimize the importance of shock is dangerous teaching.

After reviewing thousands of records, we believe that the most dangerous period of cerebral shock is approximately the first six hours. The records in the better managed cases indicate that an average of one third of all the deaths occur in this period. If the following rules concerning the management of the average skull fracture-brain injury case during the first six hours were adopted for every head injury, mild to severe, the higher mortality rates throughout the country would be reduced 25 to 50 per cent.

1 Transfer patient from stretcher to bed place between blankets and apply heat

2 Roentgenograph every head injury but never in the presence of cerebral shock

3 Do nothing which adds insult to injury. Suturing of scalp wounds or other wounds, reducing associated fractures or immediate operations are added insults which can be delayed with few exceptions

4 Don't transfer patient from ward to a more desirable room or to another hospital

5 Avoid oversedation. Don't give morphine—morphine masks the picture and adds to respiratory depression

6 Stimulate if necessary but don't depend on stimulants and sedation as sole treatment

7 Dextrose or sucrose, 50 cc of 50 per cent solution intravenously, is the best means of restoring blood volume in shock. Use an additional 200 to 300 cc of isotonic solution of sodium chloride intravenously if indicated. Overcoming the shock, not dehydration, is the sole purpose here

8 Blood plasma or blood transfusion should be used if shock is profound or hemorrhage from associated injuries is present

9 Oxygen will tide many a patient over this dangerous six hour period

10 Postural drainage or the use of an aspirator is always indicated when the air passages are obstructed

11 Antitetanus, antgas and other preventive serums may add the additional insult. Use after the first six hours when indicated

12 Watch and record pulse, respirations and blood pressure every thirty minutes to one hour, and temperature every one to two hours, observe changes in pupils and reflexes and watch for focal signs. In no other way can one chart the course and guide subsequent treatment

The breaking of these rules was noticed with increasing frequency as one reviewed the records from the good to the poorly managed cases. The immediate suturing of the scalp wounds, often with the patient dying within one or two hours, was not infrequent. The rule concerning the delayed roentgenographing of the skull usually was observed in the good management group while frequently broken in the other two

groups. Associated injuries seemed to hasten the x-ray procedure. Instead of having the fractured extremity protected with some form of temporary splinting, several patients were transferred immediately from the emergency room to the x-ray laboratory. In such instances not only the suspected extremity but the skull invariably was roentgenographed. If one feels compelled to ascertain the nature of a skull fracture or its possible location over the middle meningeal arteries, a portable x-ray machine should be used. Otherwise x-ray examination can be delayed for days.

Major procedures such as the reduction of a fractured femur or humerus or the amputation of a crushed extremity, as well as the minor procedures of suturing lacerated wounds, are definitely contraindicated in cerebral shock and especially in the presence of profound shock accompanying associated injuries. The exception to this rule may be the occasional ruptured viscera with its life threatening hemorrhage. Painful experience and a review of these records prove this statement.

Oxygen may tide many a patient over this dangerous first six hour period. With continued unconsciousness and with the gradual development of cerebral ischemia and anoxia, oxygen is always indicated. Never delay its use until it is attempted as a final resort.

Stimulants are indicated at times to meet extreme symptoms. In many a case record in the poor management group these combined with sedation constituted the sole treatment. Of all the stimulants used, caffeine ranked first. In the presence of severe shock caffeine with sodium benzoate is our choice of stimulants, in the presence of persistent low blood pressure we rely on neosynephrin. Atropine or nikethamide may be indicated when respiratory failure is threatened.

The immediate use of preventive serums was noted in many charts even when the signs and symptoms indicated probable inevitable death. We delay the use of these until the end of twenty-four hours, fearing that even their slight insult may tip the scales against the patient during this critical period. Several of the charts showed the administration of antimeningococcus serum, although it is known that the pneumococcus is the offending organism far more frequently than the meningococcus. In the last two or three years sulfonamide derivatives appear frequently in the records as a prophylactic measure. The incidence of meningitis in the collected series was 1 per cent. There may be an occasional case requiring such preventive measures, but we doubt the value of their routine use.

SEDATION

What is one to do for the extremely restless or delirious patient or for the severe headaches so frequently complained of? Sedation may relieve this situation temporarily, but beyond a question of doubt it increases the death rate. The swelling and compression of the component elements inside the skull, referred to as increasing intracranial pressure, account for these signs and symptoms. They can be relieved often permanently by the intravenous injection of 50 cc of 50 per cent dextrose or sucrose or by the drainage of 30 to 60 cc of spinal fluid. Delay of their use until medullary compression is established accounts for their ineffectiveness.

Reviewing each individual record when sedatives were used in each of the three management groups revealed that morphine invariably increased the mortality rate over the normal rate for that particular group. Thus, in hospitals A to D morphine was used in 2 to

21 per cent of the cases. The gross mortality rates in this group varied from 17 to 21 per cent, while the mortality rate among their patients receiving morphine was 25 per cent. Compare this with hospitals J to S, where morphine was used in 30 to 82 per cent of the cases. The gross mortality rates in this management group varied from 30 to 42 per cent, while the mortality rates among the patients receiving morphine varied from 36 to 50 per cent.

If not used too often or not too large doses and especially if not combined with morphine the following

TABLE 5—Mortality Rates in Oversedation

Group	Per Cent Oversedation	Death Rate for Group	Death Rate in Oversedation
Good management	3%	17.91%	14%
Average management	7%	23.29%	17%
Poor management	13%	30.49%	40%

drugs in the order named seemed to have the least deleterious effects: barbiturates, codeine, paraldehyde, chloral or chloral and bromides.

Table 5 indicates the effect on the mortality rate whenever oversedation was present. It was noteworthy that those surgeons who used sedatives early usually continued their use. Combined with neglect of good therapeutic measures, sedation is especially malignant.

TREATMENT AFTER SIX HOURS

Much that has been said relative to the management of the brain injury case during the first six hours applies during the subsequent hours and days. The only routine rules applicable to these patients are a class are:

1. Conserve the patient's strength. Feeding must not be neglected. If the patient is unconscious or won't eat, start stomach feedings with a diet similar to No. 1 or No. 2 ulcer diet, certainly not later than forty-eight hours after admission. Continue to avoid undue moving and all unnecessary measures which may add insult to injury.

2. Maintain a fluid balance compatible with life but don't push fluids unless the frailty of the patient, excessive perspiration or some associated injury, for example, a severe burn, demands more than the normal intake. In such instances it may be necessary to counteract the overdehydration by more frequent spinal punctures. If the condition of the patient warrants limitation of fluids to as low as 1,000 cc for the first twenty-four or forty-eight hours, it would be wise to increase this to 1,500 to 2,000 cc thereafter in order to maintain body fluid balance. An average intake of 1,500 to 2,000 cc is safe and applicable to most patients.

3. Charting the intake and output is exceedingly important but quite difficult when incontinence is present. Blood chemistry, especially observing the blood sugar and blood chlorides, should not be neglected and when abnormal should be controlled.

4. Early urinalyses and blood counts are essential and charting the course implies continued observation of these. Do serologic tests on the cerebrospinal fluid whenever obtained.

5. Every unconscious patient must be closely observed for retention of urine and if it is present, catheterization is necessary. If persistent, tidal drainage may be indicated. A distended bladder accounts for the extreme restlessness presented by many of these patients.

6. Daily bowel movements are essential and if dehydration by hypertonic dextrose is being practiced, several bowel movements per day will prevent the dangers of a reverse osmosis.

All treatment directed toward the increased intracranial pressure or other specific brain damage must be individualized. The signs and symptoms of each individual case suggest the possible craniocerebral pathologic condition present and the line of treatment

indicated. Patients do not all need dehydration or spinal punctures, and certainly all patients do not need operative management.

As early as 1931 the senior author classified his skull fracture-brain injury cases into four treatment groups as indicated by the signs and symptoms which influenced the type of treatment given. In analyzing these 3,106 cases they were likewise grouped according to the treatment given. The plan of placing each case in one of the four treatment groups has enabled us to compare the results of the various methods of management as judged by their mortality rates (table 6).

GROUP 1

Mild concussion is the pathologic condition suggested by the signs and symptoms in group 1. There may be mild shock combined with a momentary loss of consciousness or only a short period of being dazed, confused or semistuporous. The x-ray examination reveals a skull fracture, or a short period of bleeding from one of the orifices indicates a basal fracture.

The treatment consists of rest in bed only for a minimum of two weeks. Rest treatment only is absolutely contraindicated when patients later develop signs and symptoms demanding more drastic treatment. No patient should die in group 1. Table 6 shows entirely too many patients receiving no other form of management but rest in the average and poor management groups. Twelve of their patients died in group 1. Reviewing the charts of these disclosed that early institution of proper management should have saved at least 10, thus reducing the mortality rates of these two management groups materially.

GROUP 2

Severe concussion or mild contusion probably with microscopic lacerations and petechial hemorrhages or with localized swelling or edema or with a less pronounced generalized edema, all giving a certain degree of increased intracranial pressure constitutes the pathologic lesions indicated by the signs and symptoms of the patients who remain in group 2 throughout the course of their treatment.

TABLE 6—Comparative Results of Good, Average and Poor Management

Hospital	No. of Cases	Group 1 Rest Only	Group Dehydration	Group 3 Spinal Puncture	Group 4 Operation	Death Rate
Author	361	1%	30%	30.5%	5.5%	16.8%
Good Management	373	2% to 18% Average 8%	11% to 18% Average 7%	18% to 30% Average 20%	4% to 7% Average 5.5%	11% to 21% Average 16%
Average Management	204	5% to 18% Average 11%	4% to 76% Average 50%	14% to 30% Average 25%	4% to 7% Average 10%	9% to 29% Average 19%
Poor Management	750	5% to 37% Average 16%	10% to 77% Average 51%	10% to 44% Average 28%	5% to 30% Average 9.5%	30% to 47% Average 38%

The incidence of proved skull fractures remaining in group 2 was 50 per cent in our cases and 36 per cent in the good management group. The latter group resorted to lumbar puncture 14 per cent more frequently than did ours. Reference to table 4 indicates the inadequacy of the dehydration methods in the average and poor management groups.

Group 2 treatment includes therapeutic measures varying from shock treatment, mild sedation or stimulation to the most drastic dehydration and supportive management. The need for each procedure is gauged

by the signs and symptoms of the individual patient. Let us assume that the average patient has received his 50 cc of 50 per cent dextrose to help overcome shock. If some form of disturbed consciousness is still present, if the pulse and respirations remain slow or have a tendency to increase, if the diastolic pressure drops to 60 or below or if restlessness is the chief sign or headache the chief symptom, the 50 cc of 50 per cent dextrose is repeated in three to six hours combined with 4 ounces (120 cc) of 50 per cent magnesium sulfate by rectum. If the symptoms and signs disappear no further dextrose is administered although magnesium sulfate by rectum is continued for two or more days to prevent recurrence of increased intracranial pressure. If such signs persist but are not too prominent the dextrose-magnesium sulfate therapy may be repeated in six or twelve hours and thereafter only as indicated by the signs and symptoms.

In a review of the hospital records it was evident that many surgeons routinely order 50 cc of 50 per cent dextrose or sucrose every six hours or twice a day and continue this indefinitely regardless of the signs and symptoms. This is abusive use of these otherwise valuable agents. Again, many of the records in the average and poor management groups showed some form of dehydration used in a "hit or miss" manner regardless of indications. Frequently the hypertonic solutions were not started until the second day and were then persisted in until the patient died, although the signs and symptoms long since suggested the need of spinal drainage. These faulty inadequate methods rather than dehydration per se should be condemned.

Among the collected cases in which hypertonic solutions were employed intravenously, 50 per cent dextrose was the choice in 82 per cent against 18 per cent for sucrose, indicating the choice of the profession. Magnesium sulfate by mouth or by rectum was often the sole dehydrating agent. Ten per cent magnesium sulfate solution intravenously was used in 0.5 per cent and intramuscularly in 1 per cent of the cases. Most of these cases were fatal. Oldberg¹¹ has been especially vehement in condemning magnesium sulfate intravenously.

The use of concentrated serum has been suggested as the newest dehydrating agent in brain injuries. J. W. A. Turner¹² has reported on this method as used among the British wounded soldiers.

Several recent articles indicate a growing tendency to depend on 50 per cent magnesium sulfate in 4 ounce doses by rectum or through a Levine tube as the only dehydrating agent used. If this fails to relieve symptoms an early lumbar puncture with spinal drainage is advocated.

GROUP 3

Severe contusions, lacerations and hemorrhage, usually involving directly or indirectly the more vital centers of the brain, are the pathologic lesions suggested by the signs and symptoms of those patients who sooner or later fall into group 3 treatment. One must now think in terms of the three elements inside the bony cast the skull. The brain swells (whether this is a true edema or otherwise is an academic question), the changed physiologic mechanism causes an increase in the amount of cerebrospinal fluid, the pressure out-

ward of these two elements against the bony cast reduces inflow of arterial and outflow of venous blood. The presence of a depressed fracture or of hemorrhage may further alter the volume of one or the other of these three elements. If these pathologic changes are allowed to persist, death will follow from a compression of the vital centers in the medulla, or the overweight of the swollen brain will push its stem through the only orifice for escape, the foramen magnum—a form of herniation more to be feared than one from a spinal puncture.

The earliest possible relief of the cerebral edema, anoxia and especially the suppressed circulation is the

TABLE 7—Treatment in Five Hospitals

Source	No of Cases	Gross Death Rate	Per Cent			Average Amount Fluid Drained	Death Rate in Group 3
			Per Cent Lumbar Punctures	Punctures First 24 Hrs	Punctures		
Authors	361	16.8%	35.5%	84%	40 cc	17.6%	
Hospitals A and B	184	18.5%	70%	80%	40 cc	21%	
Hospital H	142	25.4%	32%	66%	25 cc	37%	
Hospitals R and S	112	41%	19%	20%	7 cc	78%	

aim of treatment. Dehydration will limit and reduce a certain amount of the cerebral edema. Oxygen will overcome some of the cerebral anoxia. Spinal drainage of a sufficient amount of fluid, usually bloody, to make more room for the entrance of arterial and the escape of venous blood is the only method left to relieve the severe ischemia. All three modalities are indicated in this extreme picture of brain injury. Doing a lumbar puncture as a last resort begets failure.

Certain spinal puncture axioms have been published by the senior author, for example:

1 The earlier spinal puncture is performed, when indicated the lower the death rate. Regardless of the manometer reading a sufficient amount of spinal fluid must be drained to relieve if only temporarily, the ischemia.

2 Spinal puncture is rarely indicated during the shock period but there are occasional exceptions to this rule.

3 Repeating spinal punctures and neglecting operation when definitely indicated increases the death rate.

4 Dehydration methods continued after a spinal puncture is performed often obviates repeating punctures, but do not raise the blood volume too soon after drainage.

Table 7, which includes a more detailed study of five hospitals representing each of the management groups and our cases, graphically illustrates the truths of these axioms.

Indications—When to use spinal drainage and when to repeat the procedure depends altogether on the persistence of the signs and symptoms or their increasing severity. To judge these requires the closest observation. These indications are:

1 If the unconsciousness persists, if restlessness, delirium or convulsions, twitchings or spasticity appear and persist or grow worse early spinal drainage is indicated. Repeat the procedure any time thereafter when the recurrence or the persistence of these conditions indicate, certainly within eight to twelve hours.

2 If in spite of attempts at relief with dehydrating agents the diastolic pressure remains persistently low or the systolic pressure becomes erratic and the pulse pressure persistently climbs above 65, spinal drainage should be done without further delay. High blood pressure prior to the injury may confuse these signs.

3 If the pulse and respiration are persistently rapid, especially following a period of slowed pulse and respiration, or if Cheyne-Stokes respiration develops, do not depend on dehydration but turn to spinal drainage.

¹² Turner, J. W. A. Concentrated Serum in Head Injuries. Lancet 2: 557-558 (Nov. 8) 1941.

4 If focal signs develop or if the signs and symptoms persist or grow worse in spite of spinal puncture and especially if xanthochromia persists in the spinal fluid, suspect extradural or subdural hemorrhage and strongly consider the advisability of exploratory decompression

GROUP 4

The pathologic conditions suggested or actually seen in this treatment group consists of (1) Definitely depressed skull fractures, simple and compound, (2) extradural hemorrhage, (3) subdural hemorrhage or subdural collection of fluid—often persistent late signs, (4) brain abscess—a rare and late development—and (5) persistent dural leaks—a rare operative indication

The incidence of the aforementioned pathologic conditions in proved skull fractures varies from 15 to 20 per cent as judged by the clinical and autopsy findings in the collected cases. Many of these patients died within the first few hours. The extensiveness of the lesions or the immediate critical outlook indicated that the condition of between 5 and 10 per cent of the patients in this group could not be considered operable. Experience has taught that immediate or first few hour operations are rarely successful. The incidence of operability in group 4 is probably between 7 and 10 per cent

The study of all the collected records showed many patients with definite signs of extradural or subdural hemorrhage, treated by dehydration or spinal drainage, who lived more than twenty-four hours but never received the benefit of exploratory decompressions. Several patients with depressed skull fractures died without operation. Many have stressed the importance of delaying operative procedures on depressed skull fractures. It should be emphasized that a certain percentage of these depressed fractures have a large blood clot beneath them and, when the signs and symptoms indicate the need, these must be operated on early, the operation seldom being necessary within the first twelve to twenty-four hours. The remaining depressed fractures can await the safer period of days or weeks before operation is performed. Many slightly depressed fractures, especially if located away from motor areas, may never require surgery.

Several of the compound depressed fractures, some with escape of brain substance, were operated on immediately, as shown by the case records. The majority of the patients died. In the presence of profound cerebral shock it is far wiser to cover these terrific compound fractures with sterile dressings firmly bandaged and strive to save the patient's life rather than follow a more or less routine teaching to the effect that compound skull fractures demand immediate operation. The majority of these should be thoroughly cleansed and a thorough debridement done with a minimum of necessary reparative work sometime within the first twenty-four hours. Govern the time and extent of operation by the patient's chances of recovery, not by any fixed rules.

The reaction against the promiscuous trephinnings and subtemporal decompressions of two decades or more ago has been so great that we are in danger of the pendulum swinging too far toward conservative non-operative treatment. Operative rates as low as 4 per cent, found in many of the hospital series studied, increase the mortality rate almost to as great an extent as operative rates as high as 20 to 25 per cent, found in the records of two of the hospitals.

CONCLUSION

1 Two surveys were made of the management of skull fractures and brain injuries throughout the profession, covering 6,544 consecutive cases collected from all sections of the country. The study of these records combined with our experience in 487 personal cases strengthens our convictions concerning the value of moderate dehydration, spinal drainage when indicated and the definite need of operations in approximately 8 per cent of all skull fractures.

2 The management of acute brain injury will always be a problem for the general physician and surgeon. The widespread distribution of this trauma and the fact that of all those dying 47 to 64 per cent die within the first twenty-four hours explain this fact.

3 Comparing the first nationwide survey of records collected from 1928 to 1935 with the second nationwide survey covering the five year period 1935 to 1940 shows an average reduction in mortality rates of 7 per cent in the latter. Certain hospitals previously surveyed showed as much as 50 per cent reduction in their death rates.

4 The observance of rules and indications for management of brain injury cases will in our opinion, reduce the higher mortality rates 25 to 50 per cent. Examples of poor management drawn from hundreds of the collected charts substantiate this statement.

5 It is hoped that this clinical investigation will disperse the confusion concerning management that exists in the minds of many surgeons seeing only occasional cases of brain injury.

ABSTRACT OF DISCUSSION

DR. MAX M. PIET, Ann Arbor, Mich. On many controversial points I am in agreement with the authors. I teach my students that we have certain general principles in the treatment of head injuries, but no rules. I feel that every case should be considered individually. It is impossible in the treatment of skull fractures with a wide variety of brain injuries associated with them to lay down any hard and fast rule. A most important factor in the treatment of acute head injury is immediate clearance of the air passages. Many of the patients come in with pulmonary edema already developed or they have been vomiting and there is vomitus in the pharynx, sometimes down into the trachea. The most important immediate treatment is clearance of the air passages and one can do that quickly by dependent drainage. Bring the patient clear over the end of the bed, irrespective of his general condition. Then further drainage can be kept up by aspiration. Comparatively few of our patients are in shock when they come in. I agree with the authors that when shock is present it should be treated, probably by blood transfusion. I think that is the most efficient method. I do not believe in taking roentgenograms immediately. Many patients do not have them until they are ready to go home, when the x-ray examination is made largely for a matter of record and possible medicolegal complications. The line of immediate treatment is not going to be influenced by any x-ray examination. Spinal drainage at times is a life saving measure. I have performed spinal drainage immediately on a patient being admitted when I thought that the respiratory system was failing rapidly. Immediate relief of intracranial pressure may save a life. I have done many a spinal drainage within ten minutes, perhaps, of the time the patient received his skull fracture. Seldom does one have that opportunity, but at times it is a life saving procedure. But remember that many patients with head injuries are restless because they have not urinated. A full bladder can cause just as much restlessness in an unconscious patient as in one who is conscious. Time and again I have seen patients who were difficult to control quieted at once by catheterization. When the patient is in good

condition, I believe in X-ray examination. The patient should always be examined carefully for associated injuries, which so frequently are missed because a skull fracture attracts more attention. One should therefore consider each case individually, watching, and operating only when there are definite indications. I never do subtemporal decompression simply to relieve increased intracranial pressure, but if this patient comes in with a weak arm and examination in another hour or two hours or the next day shows that that arm is now paralyzed I believe that exploration of the opposite side is indicated. I watch the pupils very carefully. The mortality can be lowered if we follow these general principles.

Dr ERN M. DOUGLASS, Toledo, Ohio. This presentation does not dispute the argument that the specialty of brain injuries is best served by specialists in that area of medicine. But it does recognize one central fact that supply and demand in this specialty do not balance. There are far more cases of brain injury than the existing specialists could possibly handle within the sharp time limits so well defined by the authors. It follows that, when a specialist is not available, some one else will have to do the best he can. This will be the situation in about 90 per cent of the cases. In undertaking this paper the authors have been moved by a point of view which to me lies near the very soul of medicine. Facing the unavoidable, medicine is never content with reasonable results. It covets the very best results. The Mocks are speaking to the physician who may have to care for a case of brain injury regardless of his personal preferences. They give us a concise program to raise the average level of care and they prepare the way for rising standards beyond that point. The paper defines a clearcut path for the general surgeons and the hospital surgeons—the men who will have to see the great bulk of the brain injury cases. The paper does not need comment so much as it needs circulation. A copy of it should be in the hands of every physician who believes that every inch of the battle for any patient's survival should be hotly contested.

Dr A. S. LEVEN, Chicago. Injuries of the skull and the brain give the industrial surgeon plenty of headaches, because such injuries nearly always produce complications wherein the etiologic relationship of trauma to cerebral disorders is a most difficult problem. The severity of the initial head injury is no index of the outcome of the case. Some patients with severe skull fractures with bleeding from the orifices and unconscious for days may completely recover. On the other hand I have seen patients with slight blows on the head present symptoms of intracranial injury and immediate death. Furthermore, a trivial injury or blow to the head may set in motion neurologic and neuropsychiatric manifestations that may culminate in permanent disabling effects. The normal pressure of the cerebrospinal fluid is 5 to 9 mg on the mercurial manometer. If it rises over 12, a definite pathologic pressure exists. The measurement of intraspinal pressure is more important in the diagnosis of intracranial pressure than is the presence of blood in the spinal fluid. The early history of a head injury even though corroborated by roentgenograms showing skull fracture, is not of major importance and should not be stressed to the exclusion of evidence of a pathologic basis for final symptoms, and it is not a basis for reaching an appraisal of permanent disability resulting from such injury. While we must appreciate the relative weight of facts in the case, we must be guided only by the conditions actually present caused by the trauma. The development of a cranial injury follows no straight pattern or course.

Dr F. M. SUMMERVILLE, Oil City, Pa. Now the surgeons of this country have the last word in brain injury and skull fractures. Dehydration properly done there is no question about, but if improperly done there is a question. A patient with skull fracture and head injury came to our service in the early days of dehydration. His entire face was edematous, we could not see the eyes, the lips were protruding, and the nose and cheeks were greatly enlarged. Dehydration was started in the evening, and later in the night he was given a large dose of 50 per cent dextrose solution. The next morning the swelling in the face had entirely disappeared but the patient died as a result of too rapid dehydration. If one can dehydrate the outside of the skull to this extent one can dehydrate the inside of the skull. We do a lot of spinal punctures, do them early, and do them

late if necessary. If the plan laid down by the Mocks is followed carefully the death rate in many hospitals can be reduced as much as 50 per cent. We have a comparatively large number of head injuries and skull fractures in our hospital and the death rate is small as contrasted to what we previously had.

Dr HARRY E. MOCK, Chicago. Dr Peet mentioned the importance of the dilated pupil. In our series of cases 50 per cent had neither a spinal puncture nor an operation, and yet 17 per cent of these showed a dilated pupil on one side—a sign which gradually disappeared. In the 3,106 consecutive skull fracture records collected and studied, a dilated pupil was recorded in 18 per cent of the cases, yet the great majority of these were not surgical cases nor was operation indicated. I am sure that Dr Peet will agree that when other definite indications for operation exist the unilateral dilated pupil is very suggestive of the site for operation. The time when death occurs following the skull fracture and brain injury is enlightening and teaches many lessons. In the ten hospitals which made up the poor management group, with lack of close observation and often late attendance on the patient, 45 per cent of the deaths occurred in the first twenty-four hours. In the good management group 64 per cent of the deaths occurred in the first twenty-four hours. In our own series, of those dying 64 per cent of the deaths occurred in the first twenty-four hours and 60 per cent of that number of deaths occurred in the first six hours. When there is good management fewer patients will die after twenty-four hours, thus raising the early death rate. These figures indicate that we must concentrate on the management of cerebral shock, the handling of associated injuries and the other conditions which cause these first twenty-four deaths, if the mortality rates are to be lowered. These figures also indicate that brain trauma will always be the problem of the general physician and surgeon. Even if we had a sufficient number of neurosurgeons to go out to the hamlets, villages and cities where a great majority of these skull fractures occur they would not be able in most instances to arrive there during this dangerous first six hour period. Therefore the full responsibility for reducing the mortality rate in skull fractures throughout the United States falls on all of us, but especially on the general physician and surgeon.

The Surgeon and Air Raid Injuries—Whatever tends to facilitate the rapid admission to hospital of air raid casualties contributes to the more favorable outcome of the treatment, and thus, since it is believed that some 40 per cent of cases need immediate operation, it is essential that there should be no hindrance whatever to the immediate admission to hospital.

The surgeon who is dealing with these cases should have an exact knowledge of the therapeutic outlook, and a sound technique. In addition, precise and orthodox surgical methods will be required of him. He has no right to hesitate. He has to decide in a few moments on the life and future of the wounded, often under unheard of conditions of overwork and fatigue. He cannot regulate the events of even the next hour for himself or his patient. He has to act quickly and choose at once the safest and best operation. To him all wounds are alike: they are recent and appear aseptic, yet grave danger threatens. It is his duty to intervene not in consequence of existing clinical indications of sepsis, but solely because of the probability of its advent, so that the wounded may be evacuated without danger as quickly as possible. He knows that amongst those who are brought to him there are none whose wounds are negligible and that the patient who to all appearances is scarcely touched may tomorrow have a grave osteomyelitis, a spreading cellulitis or a gas gangrene. Experience has taught him that if he sends away men whose wounds have not been cleaned up or have been incompletely cleaned, some of them, after a few hours' journey, will have to undergo amputation and others will die. It is his clear duty to prevent these results by practicing a rigorous prophylaxis in all cases without distinction and his surgical sense ought to be such that it is governed automatically by the desire to preserve the patient's life, his limb and its function—Mercer, Walter, *The Immediate Treatment of Air Raid Injuries*, including the Surgery of the Upper Limb, from War and the Doctor, edited by J. M. Mackintosh, M.D., Baltimore, William Wood & Co., 1942.

PATHOLOGY AND PATHOGENESIS OF HUMAN POLIOMYELITIS

ALBERT B. SABIN, M.D.
CINCINNATI

Our knowledge of the pathology and pathogenesis of human poliomyelitis has developed slowly over a period of many years, and most of the present day concepts are still so young that they have not yet influenced to any appreciable extent studies on the pathologic physiology of the disease. The present discussion will deal with three major questions: 1. What are the essential lesions of the disease and where are they located? 2. How extensive must those lesions be to produce the paralytic disease and what is the basis for the transitory character of some of the paralysis? 3. What determines the special localization and distribution of the lesions?

The earliest students of the disease¹ were able to prove that the major pathologic change was in the central nervous system and no scientific investigator has as yet found any evidence to the contrary. Although it had been suspected by some keen observers² from

TABLE 1—Regions of Central Nervous System Most Frequently Affected in Human Poliomyelitis

1	Spinal cord and posterior root ganglions
2	Medulla—vestibular nuclei, reticular formation and nuclei of various cranial nerves
3	Cerebellum—roof nuclei (fastigium and dentate) and vermis (hemispheres negative)
4	Midbrain—periaqueductal gray, tectum and tegmentum
5	Thalamus
6	Hypothalamus
7	Globus pallidus
8	Motor cortex—especially area 4 of Brodmann

the very beginning, it was not until 1929³ and thereafter⁴ that satisfactory evidence was adduced that the primary attack in the nervous system was on susceptible neurons and that the inflammatory reaction was the result rather than the cause of the neuronal damage. In monkeys killed at various stages during the experimental disease produced by a highly virulent and adapted virus it has been possible to establish a definite sequence of events—a sequence that is found duplicated in human beings when suitable material is studied. The series of photographs reproduced in figure 1 illus-

trate the fate of a fully susceptible anterior horn cell attacked by a highly virulent virus. At *a* is shown the essentially normal appearance of the cell which was generally prevalent three days before the onset of paralysis. Cells showing diffuse chromatolysis and sharply outlined, acidophilic, intranuclear inclusions (fig. 1 *b*) generally have been found one or two days before the onset of paralysis. The process then progresses to complete acidophilic necrosis of the cell (fig. 1 *c*) and invasion of polymorphonuclear leukocytes (fig. 1 *d*), which ultimately arrange themselves over the

Fig. 1—Fate of anterior horn cell attacked by highly virulent poliomyelitis virus. *a* is essentially normal cell. *b* chromatolysis and acidophilic intranuclear inclusions. *c* complete acidophilic necrosis. *d* polymorphonuclear leukocytes invading necrotic cell. *e* neuronophagia by polymorphonuclear leukocytes. Reduced from a photomicrograph with a magnification of 1,000 diameters which originally appeared in the Journal of Experimental Medicine.¹

dead neurons to form the typical focus of neuronophagia (fig. 1 *d*). After several days the polymorphonuclear leukocytes disappear and their place is taken by glial cells. This series of changes may be taken to represent the pathologic unit of poliomyelitis, and the resulting clinical signs may be regarded as depending on the number and location of neurons so affected. Associated with this there is usually also an interstitial and perivascular infiltration with cells which vary with the stage of the disease: many polymorphonuclear leukocytes being present early and mononuclear and glial cells

Personal work discussed in this paper was aided by a grant from the National Foundation for Infantile Paralysis, Inc.

predominating later. The cells present in the meninges actually represent an overflow from the perivascular spaces and are thus secondary to neuronal damage rather than the result of a true meningitis. The so-called signs of meningeal irritation, including the familiar spasm of the muscles of the neck and back, therefore, are more properly regarded as the earliest signs of neuronal damage than the result of a true meningitis.

The next series of illustrations is intended to show the extent of neuronal destruction that may be found in the lumbar cord of human beings with different types of involvement terminating at various intervals after onset. Figure 2 represents an essentially normal anterior horn from a bulbar case with initial palatal and pharyngeal involvement terminating within twenty-four hours after onset of paralysis. Although extensive lesions were present in the medulla and the cervical cord was moderately affected, the process had not yet reached the lumbar cord. Figure 3 is also derived from

Fig 2—Essentially normal anterior horn of lumbar cord of a rapidly fatal human case of bulbar poliomyelitis. Note large number of neurons and compare with figures 3, 4 and 5. Reduced from a photomicrograph with a magnification of 36 diameters.

a bulbar case of somewhat longer duration, and one may note that, while most of the anterior horn cells are still intact, there are many foci of neuronophagia and some interstitial and perivascular infiltration. It was this type of picture, in which completely destroyed neurons are found side by side with intact, apparently unaltered, ones that suggested to some of the earliest observers that neuronal damage was not due to the edema and exudate of the inflammatory reaction. Figure 4 is from a patient with initial paralysis in the extremities and shows destruction of practically all the anterior horn cells with only a few remaining foci of neuronophagia to indicate the sites formerly occupied by neurons. Figure 5 shows the complete disappearance of almost all the neurons without even foci of neuronophagia to indicate their former sites, this lumbar cord was derived from a patient who died four days after initial paralysis of the intercostals and extremities. Although the lesions are more severe and extensive in the anterior horns of the spinal cord, the posterior horns are not altogether spared, and the dorsal root ganglions almost invariably show destruction of varying numbers of sensory neu-

rons. Figure 6 shows multiple foci of neuronophagia and interstitial cellular infiltration in a human dorsal root ganglion. It may be noted parenthetically that the pathologic changes shown in figures 2 to 6 were all

present in patients from whom the virus of poliomyelitis was isolated by monkey inoculation.

Up until very recent years the attention of clinicians interested in poliomyelitis was focused almost exclu-

tion has been paid by pathologists to the remainder of the central nervous system. Table 1 shows the regions in which neuronal lesions have been found most frequently in the human central nervous system. Of particular importance to a proper reinvestigation of the pathologic physiology of the disturbances of muscle

function in poliomyelitis are the lesions almost regularly present in the vestibular nuclei of the medulla, the roof nuclei and vermis of the cerebellum, and the motor cortex. While animal inoculation methods have revealed the presence of the virus in the motor cortex in human cases and not in the frontal or occipital regions,⁶ histo-

Fig. 6—Spinal dorsal root ganglion in human poliomyelitis. Note destruction and neuronophagia of a number of neurons and interstitial cellular infiltration.

pathologic methods have permitted a much more precise localization of the affected zones. Brodmann's map of the human cerebral cortex (fig. 7), showing the areas possessing distinctive structure, is reproduced here to

recall the location of areas 4 and 6, corresponding respectively to the motor projection and association centers of the cortex. Area 4 of Brodmann is described as "the center from which the impulses initiating voluntary movements on the opposite side of the body descend to the motor nuclei of the cerebrospinal nerves," and it is stated that the fibers arising from area 6 together with the fibers connecting this area with other subcortical regions are concerned in the correlation of postural and volitional motor control.⁷ It is particularly worthy of note, therefore, that area 4 and especially the layer of Betz cells within it have been found to be most commonly affected. Thus, Horanyi-Hechst⁸ in 1935 found lesions in area 4 in 19 of his 24 human cases, while in 3 cases there also were lesions in area 6 and in only 2 cases were any found in area 1. In 1939 Swan⁹ reported that in the cortex of the 8 human cases he studied "with one exception the only area

lesions in area 6, 4 showed a few lesions in area 1, and 2 contained very infrequent and light lesions in the frontal granular cortex, in 1 case as far rostral as the orbital gyri." Figure 8, reproduced from Howe and Bodian's report,¹⁰ shows the region around the central sulcus with lesions in the precentral (motor) cortex and none in the postcentral cortex. The presence of large numbers of polymorphonuclear leukocytes in the lesions in area 4 is indicative of their acute character and there is also other evidence that involvement of this area is

Fig 10—Destruction of most of the right anterior horn of monkey with nonparalytic poliomyelitis. Reduced from a photomicrograph with a magnification of 16 diameters which appeared originally in the *Journal of Experimental Medicine*.¹¹

secondary to multiplication of virus in the lower motor neurons of the spinal cord or medulla. There is no evidence, however, that the affected Betz cells correspond exactly to destroyed lower motor neurons. In reviewing the pathologic physiology of poliomyelitis it may be worth considering the possibility that as regards certain muscle groups the upper motor neurons concerned in initiating voluntary movement may be significantly and predominantly affected.

Next I should like to examine the pathologic basis of the mild and transitory character of some types of paralysis encountered in poliomyelitis. The desired information obviously can be derived neither from a study of fatal human cases nor from studies on the experimental disease in monkeys resulting from infection with highly virulent strains of virus which produce a prostrating paralysis. However, a relatively high incidence of nonparalytic, mild paralytic and transitory paralytic poliomyelitis is encountered in monkeys inoculated with many strains of virus of human or recent human origin. In such animals it was found, first of all, that under certain conditions the host may achieve an equilibrium with the virus before a sufficient number of nerve cells is destroyed to produce paralysis and that monkeys do not need all their anterior horn nerve cells for apparently normal function.¹¹ Figure 9a shows the upper lumbar cord of a monkey with nonparalytic poliomyelitis killed about ten to fourteen days after a probably acute episode. Extensive lesions can be seen in the anterior and lateral horns with considerable focal and diffuse cellular infiltration in the areas of outfall of cells. Under higher magnification (fig 9b and c) the majority of the remaining anterior horn cells show signs of degeneration in the form of margined Nissl substance and eccentric nuclei, although only minimal signs of degeneration are found in the nerve roots at this stage. In monkeys killed at later stages one can find complete destruction or outfall of cells in most of an anterior horn at certain levels together with a pronounced reaction of degeneration in the corresponding nerve roots (fig 10). No muscle tests to detect localized weakness were carried out on these monkeys, but their activity could not be differ-

entiated from that of normal animals. These findings may be interpreted as indicating (1) that even when actual destruction of lower motor neurons occurs the segmental distribution of the lesions may be so spotty as not to affect the major innervation of a given muscle and (2) that the virus need not necessarily destroy all the affected neurons but can also produce only partial degenerative changes from which the cell may recover. A similar situation probably obtains in the instances of spontaneous recovery from distinct paralysis. Monkeys have been studied whose paralysis disappeared in as short a time as twelve to forty-eight hours after onset.¹² When such monkeys were killed several days after apparent recovery one could still find the virus in their spinal cord and side by side with older glial foci of neuronophagia there were still present cells with chromatolysis and acidophilic intranuclear inclusions. Figure 11a shows the anterior horn of the lumbar cord of a monkey which spontaneously recovered from paralysis of both lower extremities. Under higher magnification one can see that only a few essentially normal appearing neurons (fig 11b) are present, that most of the others exhibit chromatolysis and acidophilic, intranuclear inclusions (fig 11c and d), and that some of the cells had been completely destroyed as indicated by the glial foci of neuronophagia (fig 11e). These findings are not in accord with the older but still current belief that the transitory character of some paralysis is due to the disappearance of the edema and inflammatory exudate which temporarily interfered with the function of the nerve cells. As a matter of fact pronounced edema is rarely encountered in the absence of extensive neuronal destruction, while extensive cellular infiltration may be present in the absence of paralysis and usually persists long after the disappearance of paralysis.

Fig 11—Anterior horn of monkey killed two days after spontaneous recovery from paralysis of lower extremities. Reduced from a photomicrograph with a magnification of 68 diameters which appeared originally in the *Journal of Experimental Medicine*.¹¹

The discussion thus far has dealt entirely with the activity of the virus in the central nervous system. Next we may examine what is known about its behavior in the rest of the body and the factors which determine the special localization and distribution of lesions in the central nervous system. The oft reported and undeniable presence of hyperplasia and other changes in the lymphoid tissue throughout the body and occasionally also in the spleen and liver are still only poorly under-

11 Sabin A B and Ward Robert. Nature of Nonparalytic and Transitory Paralytic Poliomyelitis in Rhesus Monkeys Inoculated with Human Virus, *J Exper Med* 73: 757 (June) 1941. Bodian and Howe¹⁰

stood. There is no evidence, however, of any pathologic changes in the muscles or peripheral nerves during the acute stage of the disease, and any change appearing later is of the type that follows destruction of the motor neurons.

A study of the distribution of virus in various parts of the body of persons dying of poliomyelitis has thrown considerable light on the tissues which are predominantly attacked in human poliomyelitis.⁹ The results of tests on 22 different tissues from each of 7 cases, shown in table 2, indicated that the virus is found predominantly in two systems: (a) in certain regions of the nervous system and (b) in the alimentary tract. Its absence from the olfactory bulbs and associated rhinencephalic centers and from the nasal mucosa indicated that, contrary to common belief, the olfactory pathway is not the usual port of entry of the virus. The almost regular presence of the virus in the walls of the pharynx or ileum or in the intestinal contents and its

respond with that expected from indiscriminate spread across the blood vessels or dissemination by way of the cerebrospinal fluid, with the ultimate localization dependent on the special susceptibility of certain cell groups.

There is no denying that some neurons are more susceptible than others to the effects of poliomyelitis virus, but many lines of evidence indicate that the part of the central nervous system first to be attacked by the virus is determined by the neural connections of the peripheral tissue from which the virus invades, and that the subsequent spread within the nervous system is dependent on the central connections of the neurons in which the greatest proliferation of the virus occurs. One is particularly impressed with this when one observes the relative distribution of neuronal lesions in various levels of the spinal cord and medulla in human cases of initial bulbar or spinal paralysis (fig. 12). In the typical primary bulbar case of short duration one finds a particularly

absence from most of the other tissues that were tested suggested that the alimentary tract may be the first site attacked by the poliomyelitis virus. Tests carried out last year by Dr. Ward and myself on various levels of the human alimentary tract revealed the presence of the virus in washed portions of the tongue, posterior pharyngeal wall, duodenum and various levels of the small and large intestines. In the experimental poliomyelitis which we produced in cynomolgus monkeys by feeding a strain of virus of recent human origin, we found the virus not only in the walls of almost the entire alimentary tract but also in the liver, spleen, kidneys, urinary bladder and certain lymph nodes as well as in the blood at the time of paralysis.¹³ Despite this widespread dissemination of the virus in these animals, the virus was in no instance present in the cerebrospinal fluid and its distribution in the nervous system was similar to that found in human beings. The distribution of lesions and virus in the nervous system of human beings and experimental animals does not cor-

relate with that expected from indiscriminate spread across the blood vessels or dissemination by way of the cerebrospinal fluid, with the ultimate localization dependent on the special susceptibility of certain cell groups.

There is no denying that some neurons are more susceptible than others to the effects of poliomyelitis virus, but many lines of evidence indicate that the part of the central nervous system first to be attacked by the virus is determined by the neural connections of the peripheral tissue from which the virus invades, and that the subsequent spread within the nervous system is dependent on the central connections of the neurons in which the greatest proliferation of the virus occurs. One is particularly impressed with this when one observes the relative distribution of neuronal lesions in various levels of the spinal cord and medulla in human cases of initial bulbar or spinal paralysis (fig. 12). In the typical primary bulbar case of short duration one finds a particularly

heavy concentration of neuronal lesions in the medulla, especially in the regions of the nucleus ambiguus, dorsal motor nuclei of the vagus and the nucleus solitarius, with a smaller number of lesions as one descends in the spinal cord so that in some instances no lesions whatever may be present in the highly susceptible lumbar cord.

In the primary spinal type of case the reverse obtains—the lesions are concentrated in the entire spinal cord and, although present, are less pronounced in the medulla. Much work still needs to be done on the neural pathways utilized by the virus for invasion of the central nervous system. Since in human beings the virus is predominantly situated in the alimentary tract, it may be worth while to consider the neural connections between it and the central nervous system (fig. 13). There is every possibility and a good deal of suggestive evidence that the virus may invade along the fifth, seventh, ninth and tenth cranial nerves from the upper part of the alimentary tract to give rise to a primary bulbar poliomyelitis. The absence of virus from the superior cervical sympathetic ganglions in

13 Sabin, A. B. and Ward, Robert. Insects and Epidemiology of Poliomyelitis. Science 95: 300 (March 120), 1942. Behavior of Poliomyelitis Virus in Cynomolgus Monkeys Infected by the Oral Route.¹⁴

6 human cases¹ and in the orally infected cynomolgus¹⁴ suggests that this sympathetic pathway leading to the upper thoracic cord is probably not utilized. As regards the cases in which the primary paralysis affects the lower extremities, intercostals and also upper extremities, it is not improbable that the visceral afferent fibers from the intestine by way of the dorsal

Fig 12—Relative distribution of neuronal lesions in bulbar and in spinal poliomyelitis

root ganglions provide the usual pathway for invasion of the central nervous system. Tests on the celiac plexus in 8 human cases yielded virus only in 1, and even in that 1 the primary paralysis was bulbar, no virus was obtained from the celiac plexus of any of 5 orally infected cynomolgus. These findings tend to

Fig. 13.—Neural pathways between alimentary tract and central nervous system. Possible routes of invasion by poliomyelitis virus. The pathways indicated by broken lines are not commonly utilized by poliomyelitis virus for invasion of the central nervous system.

multitude against the visceral efferent pathway via the collateral sympathetic ganglions such as the celiac, as a common route for the progression of virus from the intestine to the spinal cord. Finally there is every possibility that the vagal afferent and efferent pathways between the intestine and the medulla may be utilized by the virus.

CONCLUSION

I should like to stress the need for a thorough reinvestigation of the pathologic physiology of poliomyelitis based especially on the following considerations

1 The almost constant involvement of the alimentary tract and the neural connections between it and the central nervous system along which the initial invasion of the virus probably occurs

2 The irreversible complete destruction as well as the partial reversible damage to the neuron as the pathologic unit of poliomyelitis

3 The presence of varying numbers of neurons that are so affected in sensory ganglions, various segments of the spinal cord, the various cranial nerve nuclei, reticular formation and vestibular nuclei of the medulla, the roof nuclei and vermis of the cerebellum and the mid-brain, thalamus, hypothalamus, globus pallidus and motor cortex.

ATROPHY IN SKELETAL MUSCLE

DONALD YOUNG SOLANDT, MD

Associate Professor of Physiology and Acting Head of the Department of Physiological Hygiene University of Toronto
School of Hygiene

TORONTO, ONT

Mammalian skeletal muscle is served by a number of different types of nerve fibers. Some represent the central and others the autonomic nervous system. Diagrammatic representation of the component parts of skeletal muscle innervation has been attempted in figure 1. Probably only the motor nerve fibers, axons of the lower motor neuron, make functional connection with the muscle fibers. It is generally believed that these fibers, and these alone, are responsible for the control of the activity of the muscle fiber and are chiefly responsible for the trophic state of muscle tissue.

Boeke¹ and others have claimed that muscle fibers are also innervated by autonomic nerve fibers. Such connections may exist but there is no satisfactory evidence that the autonomic nervous system has any direct control over the activity of skeletal muscle fibers. Sympathetic and parasympathetic nerve fibers to blood vessels in muscle give the autonomic nervous system indirect control over muscular activity. Some influence over the trophic state of the muscle is obviously also attained by this control, or partial control, over the blood supply to the tissue. The work of Orbeli² and later of Tiegs³ indicates that neurohumoral substances released in muscle as a result of autonomic stimulation can influence muscular contraction.

When skeletal muscle is deprived of its lower motor neuron, a process usually spoken of as denervation, a number of characteristic changes in the muscle take place. Such denervation is seen in many clinical conditions, most important of which are poliomyelitis and trauma to peripheral nerves. Unfortunately both are common in normal times, but the incidence of the latter has been greatly increased in every theater of war, whether it is a battlefield, a ship at sea or a bombed city. Thus an understanding of the pathologic physi-

ology of denervated muscle, as far as it will help us adequately to treat these tissues, is of special importance at the present time

DEGENERATION OF DENERVATION

The most obvious features of the degeneration of denervation are four in number (1) atrophy, (2) fibrillation, (3) changes in chemical excitability (hyper-

usually grouped under the term "reaction of degeneration") The altered response to galvanic current and the diminished response to faradic current are very definite and are represented diagrammatically in figure 2 The polarity phenomena also associated with the reaction of degeneration are bizarre, highly variable and not usually demonstrable on the exposed denervated muscle¹⁰

All the principal features of the degeneration of denervation, that is, the atrophy, fibrillation, acetylcholine and potassium hypersensitivity and the reaction of degeneration, are probably interrelated Denny-Brown and Pennybaker¹¹ suggested that the fibrillation was the result of an increased sensitivity of denervated muscle to acetylcholine Recent experiments¹² support the view that fibrillation is the response of muscle, rendered hypersensitive to acetylcholine and potassium, to the quantities of either or both these substances normally found in the body fluids It has also been suggested¹³ that the reaction of degeneration may be linked with this chemical hypersensitivity of denervated muscle

ATROPHY

Of all the features of the degeneration of denervation, the most important from the practical standpoint is the atrophy The genesis of the atrophy remains obscure. Langley and Kato¹⁴ believed that it was an overwork phenomenon caused by the fibrillary activity The tension produced by fibrillation is much less than that resulting from the normal tonic activity of the muscle Thus, unless the fibrillary contraction is of some unusual nature, a view not supported by Hayes and Woolsey, or unless we postulate a serious interference with the circulation to the muscle, the theory of overwork atrophy appears unreasonable

Fig 1—Innervation of skeletal muscle

excitability to acetylcholine and potassium) and (4) changes in electrical excitability ("reaction of degeneration")

The atrophy or loss in weight of paralyzed muscle has been recognized since antiquity The recent work of Fischer⁴ has indicated that the muscle fibrils, which are probably the contractile part of the muscle fiber, are the structures most severely damaged by the weight loss Hines and Knowlton⁶ have made a number of outstanding contributions to our knowledge of the changes in the chemical makeup of atrophying denervated muscle Their findings indicate, among other things, that there is an absolute loss of contractile tissue and a relative and absolute increase in connective tissue during the atrophic process The continuous fine, random twitching seen in denervated muscle has been called fibrillation This activity can be seen through the skin in many cases and is very obvious when the muscle is exposed It is accompanied by action potentials, and these may be recorded as a means of evaluating the degree of fibrillation⁸ Hayes and Woolsey⁹ have shown that the fibrillary contraction starts at the end plate in a muscle fiber and, once initiated, the contraction wave travels in a normal manner Hypersensitivity to intra-arterially injected acetylcholine or potassium is always seen in denervated muscles and constitutes a change in the chemical excitability of the muscle Changes in the electrical excitability are

able fibrillary activity without greatly affecting the atrophy. Levine, Goodfriend and Soskin¹⁵ have reported that very large repeated doses of atropine will reduce both fibrillation and atrophy. In more recent experiments, as yet unpublished, we found that atropine produced reduction in atrophy but had less effect on fibrillation than had quinidine. The results of our former investigation on the action of quinidine and more recent comparison of the effect of atropine and quinidine do not support the view that the fibrillary activity produces the atrophy seen in denervated muscles.

Figure 3 illustrates the atrophy exhibited by the gastrocnemius muscles of rats when treated in three different ways.¹⁶ All points on the curve represent averages involving a number of animals. The atrophy of denervation (lower motor neuron lesion) continued until the contractile elements were nearly or completely lost. It was recompressed, at least in the initial stages, by fibrillation and a great increase in sensitivity to intra-arterially injected acetylcholine or potassium. The muscle atrophy produced by cord section (upper motor neuron lesion) progressed for a period¹ and then regressed as illustrated.¹⁸ Fibrillation was never detected, although there was a moderate increase in sensitivity to intra-arterially injected acetylcholine or potassium as long as the atrophic process was active. A similar result was obtained when the nerve supply to the muscle was left intact but the muscle immobilized by fixing the knee and ankle joints with steel pins. As shown in the chart the atrophy was somewhat greater than that obtained by cord section and showed no sustained regression.

Although the three methods of producing atrophy were fundamentally different, the course of the atrophy for the first ten days was almost identical. Fibrillation was seen only in the case of the lower motor neuron lesion but inactivity, relative or absolute, of the muscle in question was induced by all three experimental procedures. In view of this fact and the experimental comparison of the effects of atropine and quinidine already cited, it seems reasonable to attribute at least the initial atrophy to disuse rather than overwork.

After the first ten days the course of atrophy differed in the three experiments as shown in figure 3. That due to a lower motor neuron lesion progressed toward complete destruction of contractile elements while the atrophy following an upper motor neuron lesion regressed. In some cases this regression resulted in the affected muscles returning to their normal weight. The reason for the initial similarity and subsequent difference between the two types of atrophy is not understood but suggests a dual atrophic process, both parts of which are active only in the case of denervation.

These studies were initiated and are being continued in the hope that knowledge thus gained would suggest

more effective methods of treating atrophying muscle. All such therapy must be aimed at keeping the muscle in as good condition as possible pending reinnervation. The results of research already accomplished offer some direction toward this desirable goal.

The fact that the disuse produced by skeletal fixation results in a wasting which develops as rapidly as the atrophy of denervation argues that splinting should

Fig. 3—Atrophy in skeletal muscle

be used with caution. Possibly this observation indicates the rationale for one feature of the Kenny method of therapy.

An understanding of the reason for the regression of initial atrophy in the case of upper motor neuron wasting might provide a valuable lead in devising methods of treatment. Unfortunately our experiments demonstrate the fact of regression but give no indication of the mechanism involved.

Periodic electrical stimulation of denervated muscle can decrease the atrophy. Although this may be considered as evidence in favor of the theory that the atrophy is a disuse phenomenon, it is possible that the benefit resulting from the electrically induced activity is brought about chiefly by the resulting increase in the circulation to the muscle. The normal circulation through muscle depends to some extent, not as yet evaluated, on the propulsive effect of the normal rhythmic contraction of muscle tissues. Such activity is lacking in denervated muscle and the deficiency may reduce the flow of blood through the quiescent tissues.

This is simply one of many lines of investigation which are being followed at present in the hope that the information obtained will lead to new and better therapeutic procedures.

PAIN AND TENDERNESS DURING THE ACUTE STAGE OF POLIOMYELITIS

FRANK R. OBER, M.D.

BOSTON

The management of the acute stage of poliomyelitis should be a combined effort of the family physician and the orthopedic surgeon. Nursing care of poliomyelitis in this stage should be carried on by a nurse specially trained in the physical therapy aspects of the disease. Sister Kenny has demonstrated the importance of this. There is no question in my mind that in waiting until the quarantine period is over before instituting early physical therapy measures, recovery is delayed because the pain and spasm when unrelieved become more and more prominent in direct proportion to neglect in instituting such measures.

The lack of knowledge among physicians of what physical therapy means is not their fault. It is because medical students are not taught the value of this important asset in the treatment of diseases which involve joints and the neuromuscular mechanism. The information handed out to these students when joint disease and deformities are discussed, is to use baking, massage and passive exercises. They are not told about the indications, methods of application or the dangers of wrong therapy measures.

There is no disease in which so much harm can be done by the wrong application of physical therapy as in poliomyelitis. This is also true of many other conditions, for example, acute subdeltoid bursitis and arthritis.

Many surgeons believe in prolonged rest and immobilization in plaster. For many years I have taught and written about the use of wire splints applied to extremities in the position of comfort plus the use of hot packs two or three times a day. Certainly the application of any apparatus in which the extremity is forcibly corrected or constantly fixed will increase atrophy, pain and muscle spasm, thus increasing the deformity. Prolonged fixation in one position causes stiffness in muscles (both paralyzed and nonparalyzed) and joints, and delays recovery.

Sister Kenny has demonstrated that early treatment beginning as soon as the diagnosis is made results in a more rapid disappearance of pain and spasm, and, when her ideas are applied, splinting is not necessary. When using the Kenny treatment it must be an all out plan. No one should assume that this is limited only to the nonuse of measures to prevent deformities. If one does, then disasters are sure to occur.

The name poliomyelitis means inflammation of the anterior horns the result of which is a flaccid paralysis. To my mind this word has not been helpful in treating the disease, first, because so many wait for the paralysis to appear, and, second, because the damage is done before treatment is instituted. If one will take the trouble to examine a cross section of a spinal cord in an affected area forty-eight hours after the onset of the disease, one will find that there are signs of inflammation throughout all the structures of the cord.

It is impossible to see, by any stretch of the imagination, that pain, spasm in muscles, unexplained bone growth changes and vascular disturbances in the

extremities are all due to a lesion in the anterior horns. In certain cases of poliomyelitis there are also sensory changes affecting the bladder, bowel and sometimes the skin, which also cannot be explained by anterior horn changes. This lesion too does not explain the occurrence of severe and continued pain so often seen in a nonparalyzed extremity or muscle group.

The symptoms of the early stage of infantile paralysis resemble those of any acute infection, but, in addition, it will be found that there is a stiffness of the posterior spinal muscles from the base of the skull to the sacrum. There may be also photophobia and a general hyperesthesia involving the neck, back, abdomen, chest and extremities. This hyperesthesia usually comes on very early and before the paralysis appears. It is not limited to areas which later become paralyzed.

There are cases in which a diagnosis of osteomyelitis and appendicitis has been made. Quite recently I have seen two children who had normal appendices removed and who had infantile paralysis.

The superficial hyperesthesia is followed by a deep sensitiveness in any group or even in all the skeletal muscles. This pain also may not be limited to the paralyzed muscles, it may be even more severe and distressing in a nonparalyzed muscle. Patients when lying quietly in bed may appear to be perfectly comfortable until some one alters their position. On the other hand, the pain may be so severe that the slightest movement or jarring of the bed produces an attack of severe pain.

Sister Kenny points out that there is spasm in the affected muscles and also that this spasm may inhibit muscle function not only in the affected muscles but also in the antagonists. The spasm allows the affected muscle to contract and at the same time stretches the opposer, which if allowed to continue long enough, will cause loss of power in the opposer. It has been long recognized among orthopedic surgeons that a constantly stretched muscle will lose power.

It seems difficult to understand how one can have spasm in flaccid paralysis. It must be remembered, however, that it is rare for any muscle or group of muscles to be completely paralyzed. It is possible that the unaffected cells may be in spasm from some factor which at present is not quite clear to us. There is no question in my mind that there is an intimate connection between the deep muscle tenderness and the spasm which occurs so often during the acute stage of poliomyelitis.

The areas chiefly affected by spasm and tenderness are the muscles of the cervical dorsal and lumbar regions, the adductors of the shoulder, the abdomen, the calf, the knee flexors and extensors, the hip flexors, extensors, adductors and the abductors.

One of the most important aspects of the very early stage is to be able to recognize spasm and deep muscle pain. Each patient must be examined with great care and extreme gentleness or he will be treated as if he were convalescing from any acute infection. Rough handling, early massage, bad bed nursing and neglect will increase the acute condition. There are certain tests recommended by which it is possible to learn whether or not spasm, stiffness, and pain are present.

Muscle spasm may be felt and seen. Muscle soreness can be elicited by steady, gentle pressure of the muscles and by a gentle stretching of the muscles.

It is important to know how to test for tenderness. In the average case slow, gentle squeezing or pressing the muscles may elicit pain. Stretching the calf muscles

by gently, slowly and steadily dorsiflexing the foot when the leg is extended and slow, straight leg raising will result in pain in the hamstrings and buttock muscles. Attempts to straighten out flexion deformities at the knee and hip will be attended with pain.

Shoulder Hold the shoulder down from above with one hand and gently abduct. If there is sensitiveness in the adductors, pain and spasm will occur in these muscles.

Neck and Spine Place the patient on his side and flex his neck and trunk. If there is pain and spasm in the spinal muscles, the attempt at flexion will be resisted.

Abdomen To elicit tenderness, the physician should palpate the muscles with firm steady pressure until pain is exhibited by the patient.

Deformities in the early stages are due to pain, muscle spasm and muscle contractures. These are relieved by rest and the application of moist heat for prolonged periods as advocated by Sister Kenny and the maintaining of the affected parts in the position of greatest comfort. The most important requirement during this period is a nurse who is thoroughly trained in the total management of these cases.

I have stated many times in print that this is the most neglected phase of the whole disease. Bad nursing and neglect will give bad results, results which may take years to overcome or which may never be overcome. It is better to use splints to prevent some of the havoc than to have more serious deformities occur. If the splints are to be used, they must be of wire so that they can be bent to conform to the comfortable position of the legs, because, as the spasm and deep tenderness lessen, the deformities lessen, and the splints can be straightened to coincide with the deformity. Stretching must be avoided since it only increases the pain and spasm and results in more deformity.

Lovett¹ advocated warm baths in the acute phase. In fact, it was our custom to immerse these patients daily in a hot tub, the temperature being 95 to 105 F. It was noted then that their tenderness disappeared. Unfortunately, many of those patients were not seen by us for weeks after the onset. Miss Kenny starts treatment from the first day if possible. The earlier the symptomatic treatment starts, the shorter will be the period of tenderness, and the spasm ceases earlier. Gentle passive movements within the range of discomfort may be tried a few times throughout the day. The patient is encouraged to become muscle conscious during these movements.

Sister Kenny's treatment is superb nursing and common sense. Her patients show early disappearance of deep tenderness and muscle spasm, the texture of the skin is normal, flexibility of the joints comes on rapidly, and it is possible to start muscle re-education earlier. Because of these three things, early deformities are not seen in those cases under her care in the Minneapolis hospitals.

Muscle stiffness is a very common occurrence in the calf quadriceps, hip flexors and extensors, in the erector spinae muscles, and the adductors of the shoulders.

The inability of a patient to flex his trunk with his legs extended is seen very frequently after prolonged rest and prolonged muscle tenderness. This is not seen when hot packs are used continuously.

There are some who say that dry heat is as efficacious as moist, but in my experience that is not true. Cases of cerebral spastic paralysis will not relax when treated with dry heat, but will do so in hot baths. The problem then in the early stage is expert nursing, early hydrotherapy, gentle passive movements within the range of discomfort in order to prevent muscle and joint stiffness, and active exercises of groups of muscles as soon as the spasm and soreness have disappeared. The longer one puts off such measures, the slower will be recovery of muscle function.

It is not to be supposed that complete recovery will be the rule, but better and earlier recovery is better than little or no recovery. One must remember from the point of view of function that any degree of recovery may make all the difference between dependence and independence in any disease which causes crippling.

EFFECTS OF IMMOBILIZATION AND ACTIVITY ON NEUROMUSCULAR REGENERATION

H. M. HINES, PH.D.

LOWA CITY

This report is concerned with the results of experiments dealing with the effects of various conditions on the extent and rate of neuromuscular atrophy and regeneration. These include such conditions as immobilization of the limb by casts, forced exercise, electrical stimulation of the paralyzed muscle, application of cold and heat and attempts to enhance functional reinnervation through facilitation of axon bifurcation.

Most of the experiments were carried out on the gastrocnemius muscles and tibial nerves of adult albino rats and included quantitative measurements of muscle mass, strength and creatine content. Complete paralysis of the gastrocnemius was produced by crushing the tibial at the level of its junction with the peroneal. Partial paralysis was produced by removing a section of one or more of the spinal nerves contributing motor fibers to this muscle.

Quantitative studies were made as to the condition of the muscles and nerves at designated times after either complete or partial denervation. For most of the experiments the muscle and nerve of the contralateral limb not operated on served as controls. Measurements of strength were made by determining the amount of isometric tension developed by the muscle in response to stimuli applied directly to the muscle and to its motor nerve. The stimuli were of such duration, frequency and intensity as to cause maximal responses.

The course of atrophy and regeneration was found to run a remarkably constant course in this species. For a period of about two weeks following nerve crushing the muscles lost weight, strength and creatine at a rate precisely that following denervation by nerve section. The first signs of functional reinnervation, as revealed by faint contraction responses to motor nerve stimulation, appeared on the twelfth to the fifteenth day. At this time fibrillary activity, which first appeared three days after denervation, could no longer be detected. However, increased sensitivity to acetyl-

Aided by a grant from the National Foundation for Infantile Paralysis, Inc.

Read in the Panel Discussion on Poliomyelitis at the joint meeting of the Section on Nervous and Mental Diseases and the Section on Orthopedic Surgery at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

¹ Lovett, Robert W. Treatment of Infantile Paralysis. Philadelphia: P. Blakiston's Son & Co. 1916. p. 37.

choline injections persisted as long as thirty-five days after establishment of the lesion. After the onset of reinnervation the affected muscles rapidly increased in strength, weight and creatine concentration. At eighty-four days they had recovered to within 85 to 90 per cent of that in their controls. The rate of regeneration of muscle weight following reinnervation follows a

Chart 1—Average values for degree of atrophy and strength of gastrocnemius. The strength was determined from the responses to direct and nerve stimulation.

mathematical formula essentially like that for the body growth rate. The changes in muscle creatine and strength were due in part to changes in the quantity of contractile tissue present and in part to alterations in the functional state of the structural elements present.

Immobilization of the limb in a neutral position by the application of plaster casts definitely retarded recovery from the paralysis resulting from peripheral nerve injury. Immobilization had no appreciable effect on the rate or extent of atrophy prior to reinnervation. One finds the same degree of atrophy and loss of strength in the muscles of a denervated immobilized limb as in its contralateral noncasted denervated control prior to the onset of reinnervation. No evidence could be found that immobilization either hastened or retarded the extent and velocity of axon regeneration. The most striking effects of immobilization were a retardation of the recovery of muscle mass and strength following reinnervation.

On the other hand, forced activity induced by either swimming daily for one hour or exercise in a revolving barrel for two hours a day was in no instance found to be detrimental to neuromuscular regeneration. In fact the overall effects point toward the conclusion that exercise facilitates recovery from the paralysis due to peripheral nerve injury. Because of the difficulties of securing cooperation of the animal in eliciting early muscular movements following reinnervation, attempts were made to enhance the degree of muscular contraction by the use of electrical stimuli. Induction shocks of such intensity and frequency as to cause strong sustained contractions of the muscle and without doubt some degree of "overstretching" and "local fatigue" proved not to be detrimental to any phase of neuromuscular regeneration. Such stimulation for a brief period of three minutes a day greatly retarded muscle atrophy prior to reinnervation and accelerated the recovery of muscle weight and strength subsequent to reinnervation. There appeared to be a direct relationship between the intensity of the stimulus and its effectiveness in retarding atrophy which may have been due only to the number of muscle fibers activated by the stimulus.

My colleague Dr. Knowlton has investigated the effects of external temperature on neuromuscular regeneration. In one group of animals the paralyzed limb was immersed in water kept at 112 to 117 F for five hours daily. In another group the limb was immersed in ice water for the same period of time. After twenty-one days there was no difference in the strength and weight of the muscle from the animals in these two groups. They showed essentially the same extent of regeneration as in control animals. These findings should not be interpreted as evidence against the use of hot applications in the early treatment of poliomyelitis, in which the application of heat is for purposes other than the enhancement of neuromuscular regeneration.

It has long been known that axon branching occurs during the regeneration of peripheral nerves. The extent to which such axon branching may be utilized in the reinnervation of partially paralyzed muscles is a matter of controversy. Much of the uncertainty is due to lack of suitable controls and adequate methods of measuring the degrees of functional recovery.

The previously mentioned techniques have been employed in a study of partially paralyzed muscle with the view of evaluating the functional aspects of axon bifurcation. Partial paralysis of the gastrocnemius was produced by removing a section of the sixth lumbar nerve. The degree of paralysis resulting from such nerve section was determined by measuring the muscle tension which developed on stimulation of the tibial nerve after allowing four days for loss of excitability in the severed axons. These measurements were compared with the strength developed on direct muscle stimulation and with values obtained on the contralateral control limb. In a number of animals the sixth lumbar section was combined with a crushing of the tibial nerve in order to facilitate axon bifurcation and to allow for a reinnervation of motor units which had been paralyzed as the result of spinal root section.

Studies made on the muscles and nerves of animals subjected to the combined effects of lumbar section and tibial nerve crushing show that such muscles were always inferior in weight and strength to their controls afflicted only with spinal nerve section. The measure

Chart 2—Average values for the atrophy and strength of gastrocnemius from animals subjected to either crushing of tibial nerve removal of sixth lumbar or the combined lesions.

ments were made at various times and as late as eighty-four days after denervation, which is sufficient time to allow for 80 to 90 per cent recovery in muscles with crushed nerves. That axon bifurcation takes place in crushed nerves of the rat has been shown by Greenman. These experiments however, offer no evidence for its usefulness in promoting functional recovery in partially paralyzed muscles.

SUMMARY

A study has been made of the effects of various conditions on the extent and rate of recovery from complete and partial paralysis resulting from peripheral nerve injury. The criteria of recovery included measurements of muscle composition, mass and strength. Immobilization by the application of casts retard recovery from paralysis. This appears to be due to a lessened rate of muscle regeneration rather than an effect of nerve regeneration. Activity induced by forced exercise in revolving cages and swimming and electrical stimulation to the point of overstretching and even local fatigue does not appear to be detrimental to any phase of neuromuscular regeneration. The overall effects of natural and artificial activity are in the direction of an improvement in the rate and extent of recovery from peripheral nerve paralysis.

No evidence was found that axon branching could be utilized to enhance the reinnervation of partially paralyzed muscle.

THE ROLE OF PHYSICAL THERAPY IN THE EARLY TREATMENT OF POLIOMYELITIS

H. R. McCARROLL, M.D.
ST. LOUIS

A review of the medical literature during the past quarter century reveals many glowing reports on results from treatment of acute anterior poliomyelitis by numerous and widely different forms of physical therapy. In the earlier days bakes, massage and muscle training in conjunction with some form of immobilization during the acute stage only¹ were thought to offer great hope for the repair of these damaged muscles. Townsend² in 1916 stated that his best results in a New York epidemic were obtained in children kept in bed for at least one year. Judson³ advised rest and fixation for twelve to twenty-four months. During this same period both faradic and galvanic stimulation of involved muscles was strongly advocated by some. Peckham⁴ stated in 1916, "Treatment should begin at once even in the acute stage by application of heat in order to obtain a fresh influx of blood to the paralyzed muscle." He recommended use of a 500 watt electric bulb for twenty minutes, then mechanical stimulation by vibration. Later the Hubbard tank was introduced, and still later the large warm water pools replaced the tanks for under water therapy. In more recent years the Kendalls⁴ have revived the idea of prolonged fixation and protection, and their work was widely heralded as a tremendous advance in the treatment of this disease. The principles of their method were distributed in bulletin form by the U. S. Public Health Service. Now in the past two years Sister Kenny's method has risen to a position of prominence in this country and at present seems to be gaining momentum as the newest and most popular fad

All of which makes one wonder if we are not merely traveling in a circle.

In most of these instances the disease has been considered as a purely local muscle lesion, the basic lesion in the anterior columns of the spinal cord being completely ignored. It is easy to understand how physical therapists enthusiastic in their work, might lose sight of this primary pathologic process. It is impossible, however, to understand how orthopedic surgeons can wholeheartedly endorse any of these methods as a dependable means of controlling the after-effects of this disease. Our knowledge of the pathology of poliomyelitis, long recognized and often proved, should not permit us to accept and sanction unquestionably any treatment which in reality amounts to nothing more than tinkering with the peripheral secondary change in the muscles themselves.

During the years 1935 to 1941 inclusive my associates and I have seen 245 recent cases of poliomyelitis (487 involved extremities) at the St. Louis Unit of the Shriners' Hospitals for Crippled Children, in which an attempt has been made to compare results with various forms of treatment. These patients have reached a stationary level in their recovery and we are able to state definitely the degree of residual involvement which they show. For the comparative study of these results we have attempted to estimate the return of function in an extremity as a whole and compare this with the original involvement. For the initial involvement, only two classifications were used: (1) those extremities showing complete paralysis, which includes those with no muscles

TABLE 1—Summary of Fifty-Three Extremities (Thirty-One Patients) Treated by Short Periods of Immobilization of One to Four Months Without Physical Therapy

Involved Part and Degree of Original Involvement	Number	Final Rating				
		Zero	Poor	Fair	Good	Normal
Arms						
Complete paralysis						
Partial paralysis	8				3	3
Legs						
Complete paralysis	26	10	9	4	2	1
Partial paralysis	19		1	4	13	1

TABLE 2—Summary of Fourteen Extremities (Nine Patients) Treated by Short Periods of Immobilization of One to Three Months in Solid Plaster Followed by Physical Therapy for Three to Six Months

		Zero	Poor	Fair	Good	Normal
Arms						
Complete paralysis						
Partial paralysis	1			1		
Legs						
Complete paralysis	7	1	2	3	1	
Partial paralysis	6			2	4	

rated better than poor, and (2) those showing only partial paralysis with muscle gradings higher than this. For the estimated residual function in these extremities five classifications have been used:

- 1 Zero—Completely flail extremity or one with a few muscles showing no more than a trace in power.
- 2 Poor—Slight return but with muscles rated no better than poor and consequently of little or no functional value.
- 3 Fair—Fair return in most muscles and perhaps good in a few but with insufficient return in the more important muscles to permit a brace free extremity.

³ Peckham, F. E. in discussion on Lovett.¹

⁴ Kendall, H. O. and Kendall, F. P. Pub. Health Bull. 242. U. S. Government Printing Office, 1938.

4 Good—A satisfactory brace free extremity. This means at least good return in the major muscles, but with some residual involvement. Extremities with good muscles about the hip and knee but with residual involvement of muscles about the foot, are listed in this group.

5 Normal—Those extremities with no demonstrable residual involvement. The same criteria have been used in estimating the return of power in the muscles of the upper extremity except for the necessity of using apparatus. Upper extremities are frequently seen with the deltoid paralyzed while the remainder of the extremity shows little or no involvement. Such extremities have been classified as good. It is obvious that such a classification is based on a rough estimate of the residual involvement. It is justified however since the amount of function which an extremity shows determines the value of the therapy used.

For this comparative study the cases have been grouped according to the type of treatment used, and results have been listed separately for the original complete paralysis and the original partial paralysis. Table 1 shows the results in cases treated by short periods of immobilization with no physical therapy. Weight bearing was permitted as soon as the period of immobilization ceased, supportive apparatus being used if indicated.

Table 2 shows cases treated by short periods of complete fixation followed by physical therapy for from three to six months. Protection of the extremity during the period of physical therapy was maintained by plaster splints or specially prepared braces to prevent active use. Physical therapy consisted of limited active and passive motion either in the pool or on a table, in which case each treatment was preceded by brining and massage of the involved extremity. These treatments averaged about twenty minutes daily for five days each week. Temperature of the water in the pool was about 95 F.

TABLE 3—Summary of Eighty-Eight Extremities (Forty-Six Patients) Treated with Prolonged Plaster Immobilization of Four to Eighteen Months without Physical Therapy

Involved Part and Degree of Original Involvement	Number	Final Rating				
		Zero	Poor	Fair	Good	Normal
Arms						
Complete paralysis	8		1	4	2	
Partial paralysis	7			1	4	2
Legs						
Complete paralysis	57	27	14	14	2	
Partial paralysis	16		1	7	8	

TABLE 4—Summary of Seventy Extremities (Twenty-Five Patients) Treated with Prolonged Plaster Immobilization of Three to Twelve Months and Longer Followed by Physical Therapy for Eight to Twenty-Four Months

Involved Part and Degree of Original Involvement	Number	Final Rating				
		Zero	Poor	Fair	Good	Normal
Arms						
Complete paralysis	14		1	7	6	
Partial paralysis	11			1	5	5
Legs						
Complete paralysis	33	16	5	8	1	
Partial paralysis	12			1	7	4

Table 3 shows the results obtained in cases treated by prolonged immobilization for from four to eighteen months with no physical therapy. For the most part this immobilization consisted of absolute fixation in solid plaster and the remainder of the period in bivalved plasters or plaster splint.

Table 4 shows an analysis of cases treated by prolonged plaster immobilization followed, after three to

twelve months, by continued immobilization and accompanying physical therapy. Fixation of some form with no free active use of the extremity was maintained in all cases for periods of from eight to twenty-four months.

TABLE 5—Summary of Two Hundred and Sixty Two Extremities (One Hundred and Thirty Four Patients) in Which No Treatment Was Used

Involved Part and Degree of Original Involvement	Number	Final Rating				
		Zero	Poor	Fair	Good	Normal
Arms						
Complete paralysis	47	0	0	7	14	15
Partial paralysis	25			1	14	10
Legs						
Complete paralysis	106	20	24	17	37	9

Group 4 Immobilization 7 to 13 mos physical therapy 8 to 21 mo	70	0%	1%	21%	37%	1%
Group 5 No treatment	262	0%	13%	15%	47%	1%

Table 5 shows cases in which no treatment whatever was used. Some of these patients were seen by us early in the disease and merely kept in bed for various periods of time without any attempted therapy, weight bearing being permitted as soon as the patient felt able. Others were patients who lived in inaccessible communities and who usually were without the immediate services of an orthopedic surgeon or physical therapist. These patients were kept in bed only during the acute illness, and most of them were made to attempt to walk as soon as they could venture out of bed. In many instances the parents felt that the paralysis would progress unless the child was forced to use the involved extremities and exercise them as much as possible. These patients were seen in the clinic from six weeks to twelve months after onset of illness. Since these patients did not have accurate muscle charts early in the process it may be argued that considering them in this discussion is not justified. The parents, however, were questioned as to whether the involved extremity in each instance showed complete or partial paralysis. This was determined by whether or not the patient lost all ability to move the extremity in question. If the extremity could not be actively moved, it was felt safe to assume that there was extensive involvement and to classify it as completely paralyzed. When some ability to move the extremity remained, the involvement was listed as partial paralysis.

Table 6 shows the results in each group without classification according to the degree of involvement. From this it can be readily seen that no particular form of therapy produced results that were outstanding. In fact the highest percentage of satisfactory brace free extremities occurred in that group of patients who received no treatment during the early stages and who began to walk without support as soon as they could get

out of bed. The degree of initial paralysis was of far greater value in determining the degree of residual involvement than was the type of treatment used. Classifying all groups together, there were 298 extremities showing complete paralysis at the onset, and 189 extremities showing only partial paralysis. Final rating in each of these is shown in table 7.

From these findings it seems safe to assume that the results in anterior poliomyelitis can be more adequately explained on the basis of the underlying pathologic process than on the basis of the early treatment used. Initial paralysis in many instances is due to a block in the pyramidal tracts from localized edema, congestion and cellular infiltration without actual destruction of the ganglion cells. Such a paralysis is temporary in character, and muscle function returns with relief of pressure from the anterior horn cells with the subsidence of the edema. Instances of only partial paralysis of an extremity in the beginning can easily be explained on this basis and could account for their higher percentage of satisfactory results. Those extremities showing satisfactory functional return, in spite of apparent initial complete paralysis, can also be explained on this basis. If, however, the anterior horn cells are actually destroyed, the muscles supplied by those nerve cells will remain completely paralyzed regardless of the type of treatment.

In this study there have been no cases treated by the Sister Kenny method. It has been my privilege to visit briefly the various hospitals in Minneapolis and see some of the cases treated under Sister Kenny's supervision. From the standpoint of symptomatic treatment in the acute stage this method may offer definite advantage, but it falls far short of supplying the answer to our problems in this disease. Sister Kenny prefers to consider the local muscle involvement as the primary pathologic process and feels that the damage to the spinal cord is of secondary importance. She will admit, however, that spinal cord damage does exist in those patients who show persistent residual involvement. Muscles that have previously been considered paralyzed

TABLE 7—Results for Groups Combined According to Degree of Original Involvement

Degree of Original Involvement	Total No.	Zero	Poor	Fair	Good	Normal
Extremities with initial complete paralysis	298	16%	21%	22%	22%	9%
Extremities with initial partial paralysis	189	0	2%	18%	67%	15%

she prefers to consider as merely alienated because of the spasm existing in opposing groups as a result of their involvement, i. e., the muscles we have originally considered involved she considers satisfactory but merely alienated. She uses as proof the fact that these muscles later show evidence of return even though they may never attain more than a trace in power. She refuses to admit that this could be due to restitution of function in a few of the ganglion cells. Since such ideas cannot be reconciled to our present knowledge of the proved pathologic process in this disease, and since many of her patients also show residual paralysis and even flail extremities, I feel certain that this method in time will take its place among the others offered by the field of physical therapy as having been tried but found wanting.

Vast sums of money have been raised in this country in recent years for carrying on the fight against poliomyelitis. Much of this money has been and is still being devoted to continuation of physical therapy and to

follow-up studies on the results of this treatment in various clinics. This seems strange in view of the fact that physical therapy has repeatedly made fabulous claims for one method or another but has yet to offer a treatment that has been able to stand the test of time or which can be justified from the standpoint of the pathologic process involved. Physical therapy will never prove to be the answer to our problems in this disease. The control of poliomyelitis will undoubtedly some day be brought about through its prevention and not through its cure, and the sooner more of our available funds are used for research work in the field of immunology, the sooner our investment will begin to yield satisfactory returns.

SOME PUZZLING ASPECTS OF PAIN IN THE CHEST

TINSLEY R. HARRISON, M.D.
WINSTON-SALEM, N. C.

Our present knowledge of the causes of pain in the chest is rather meager. This is in contrast to the situation as regards abdominal pain, and the explanation for the difference is probably to be found in the frequency with which patients presenting obscure abdominal pain are subjected to surgical exploration. Thus the cause of the pain is determined and the disease process is correlated with the patient's symptoms. When there is an obscure pain in the chest the diagnosis can frequently be arrived at only by autopsy, which is carried out in a relatively small percentage of cases. Nevertheless the results of thorough clinical study are not altogether fruitless in such cases, and it is with some findings arrived at by this method that I wish to deal here.

When approaching a patient with chronic pain in the chest one should remember that there is only one common serious cause, i. e., disturbance of the coronary circulation. Most of the other common causes are of trifling significance. Thus the physician is faced in most instances with the necessity for making a decision as to whether the patient has an inconsequential condition or a mortal disease. Hence, when there is pain in the chest the first question to be answered is: Is this pain due to deficiency of the oxygen supply to the heart, i. e., if acute, is it due to coronary thrombosis or, if chronic and recurrent, is it due to angina pectoris?

The answer to this cardinal question was difficult to arrive at a generation ago but this is no longer the case. The classic studies of James B. Herrick¹ on coronary thrombosis and the publication of Keefer and Resnik² on angina pectoris clarified the confusion surrounding these subjects and it is now possible to recognize both of these conditions with a rather high degree of accuracy. Indeed, one gains the impression that both conditions are now diagnosed more frequently than they exist, a state of affairs which is just the opposite to that prevailing a generation ago.

From the Department of Internal Medicine, Bowman Gray School of Medicine of Wake Forest College.

Read before the Section on Miscellaneous Topics, Sessions on General Practice at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

¹ Herrick, J. B. Clinical Features of Sudden Obstruction of the Coronary Arteries. *J. A. M. A.* 59: 2015 (Dec. 7) 1912.

² Keefer, C. S., and Resnik, W. H. Angina Pectoris: A Syndrome Caused by Anoxemia of the Myocardium. *Arch. Int. Med.* 41: 769 (June) 1928.

Once the decision has been made that the pain of a given patient is not of coronary origin, i. e. once we know what is not causing the patient's pain, the next problem is to discover what is causing it. My purpose in the present communication is to discuss a series of conditions which bear either a close or a superficial resemblance to the pain of coronary disease and to mention some of the points which have seemed to be of value in differential diagnosis. No attempt will be made to give a comprehensive survey of all the conditions which may cause chest pain, as such a survey would necessitate a much more detailed discussion.

SOME CONDITIONS COMMONLY CONFUSED WITH CORONARY THROMBOSIS AND ANGINA PECTORIS

Since the pain of myocardial anoxia may be felt in almost any region between the nose and the navel, it may be simulated by a great many disorders. Ordinarily the resemblance is only superficial, but there is a group of disorders which is likely to cause confusion. I shall not attempt to deal with all these but only with some which have occasionally proved exceptionally difficult.

1 Myalgia and Arthralgia in the Region of the Left Shoulder.—These conditions do not ordinarily cause difficulty, because the pain is related to movements of local parts rather than to general exertion, such as walking. Occasionally, however, a person with such disorders will complain of pain on walking, and one finds that this pain is due to the swing of the arm, being absent when the patient walks with his left hand in his pocket. More confusing are the rather frequent instances of patients who develop "muscular" pain in these structures in association with coronary disease. Such pain, which is perhaps dependent on reflex muscle spasm resulting from the disease of the heart, may be associated with local tenderness over the pectoral or deltoid muscles and may be aggravated by abducting or lifting the arm. Patients with angina pectoris not infrequently have such a pain, which occasionally may be more troublesome than the substernal pain of effort. In all middle aged and elderly subjects complaining of a pain in the left arm, one must make a careful study for the possible presence of angina pectoris, even though the pain presents all the characteristics of muscular pain. Discomfort of this type is frequently observed in patients with coronary disease. An instance follows.

CASE 1—A man aged 62 came to have his heart examined because of pain in the region of the left shoulder. He stated that this pain was not related to walking but was brought on by bending over and picking up objects with the left hand or by putting his left hand on the back of his head. He was fearful of heart disease because a relative had recently had an attack of coronary thrombosis associated with pain in the region of the left shoulder.

On examination there was tenderness to pressure in the muscles of the upper aspect of the left arm. The blood pressure was 166 systolic and 102 diastolic. The heart was negative to physical examination and within normal limits by fluoroscopic examination. An electrocardiogram revealed no abnormality except left axis deviation. The patient at first stated that he did not have any discomfort on walking except for slight dyspnea on rather severe exertion, but more careful questioning revealed that on one occasion about two months before, while walking up a steep hill against a cold wind, he had had some substernal heaviness. The story was rather vague and he was not very clear about this particular episode. Exercise was therefore carried out under observation. Walking up two flights of stairs at a fairly brisk rate caused a

little panting but no feeling of pressure or other distress. However, walking up four flights of stairs induced a feeling of constriction, with a mild cramplike pain beneath the sternum and in the suprasternal notch. Repetition of the same exercise after the administration of $\frac{1}{2}$ grm (0.0003 Gm) of glyceryl trinitrate caused no such distress, although the panting was again induced. A year later, while attending a social function and feeling in excellent spirits, the patient suddenly died.

In this case the existence of what seemed to be a typical myalgia furnished the clue which led to the detection of angina pectoris. Although one might think that the two conditions were coincidental, they occur so frequently together as to give rise to a belief that the shoulder pain may be due to muscle spasm induced reflexly by the disease of the heart.

2 Spinal Arthritis.—As a rule this condition does not cause confusion with the pain of coronary disease. However, occasionally the two occur simultaneously. The following case illustrates this association.

CASE 2—A woman aged 73 had mild congestive heart failure, auricular fibrillation and pain in the upper lumbar and lower dorsal regions which was definitely related to movements of the body. Walking induced dyspnea but no pain. The back was rigid with considerable muscle spasm and the x-ray examination showed advanced hypertrophic arthritis in the lumbar region. The cardiac condition responded satisfactorily to treatment. A year later the patient was seen again and at this time she stated that her low back pain was still present and that she now also had pain high in the back of the chest and in the back of the neck. This pain was not related to movements of the head or of the spine although such movements still caused pain in the lower back. On the other hand walking, which did not affect the pain in the lumbar region, induced the pain in the upper dorsal region and the back of the neck. This discomfort was relieved by glyceryl trinitrate, which did not affect the low back pain. The electrocardiogram now showed depression of the S-T interval in the fourth lead, this change not having been present the previous year.

In an elderly patient with known chronic spondylitis, the development of a new site of back pain naturally led to the suspicion that this too was dependent on spinal arthritis. The presence of auricular fibrillation, which is very rarely found in association with angina pectoris,³ might seem to constitute evidence against the cardiac origin of the pain. However, the relation of the pain to walking, its relief by glyceryl trinitrate and the associated electrocardiographic changes seemed to leave no doubt that the patient had angina pectoris. It is not unusual for a patient with this disease to have substernal distress associated with discomfort in the back of the neck. However, in occasional patients, such as the one cited, may have the pain of angina pectoris only in the latter region.

3 Pericarditis.—Acute inflammation of the pericardium, when associated with the accumulation of purulent exudate or when due to tuberculosis or rheumatic fever, is not likely to be confused with coronary disease. There is, however, a type of pericarditis which commonly leads to an erroneous diagnosis of coronary thrombosis. This occurs most frequently in the winter months and especially in individuals who have had a recent respiratory infection. The onset is usually sudden, but the pain is more likely to be stabbing and to be intensified by breathing and is usually less constrictive in character than the pain of coronary thrombosis. Except for this the two conditions simulate each other very closely, both being associated with fever,

leukocytosis and somewhat similar electrocardiographic changes. Cases of this type have been described in detail recently by Barnes.⁴

CASE 3—A man aged 37 developed a pain in the region of the lower sternum. This pain was aggravated by breathing. Within four hours after the onset of the pain his temperature was 102 F and the leukocyte count 13,000. On the following day there were minimal signs at the base of the right lung, these consisting of questionable dullness and some diminution in breath sounds. An electrocardiogram was negative. Following the administration of sulfathiazole his elevation of temperature suddenly diminished. Ten days later the pain recurred, slightly to the right of the sternum. This pain also was worse with respiration and striking in character. The following day a pericardial friction rub was heard and an electrocardiogram revealed inversion of the waves in leads 1, 2 and 4. He improved rapidly but continued to have slight fever for several months.

In this case the illness resembled coronary thrombosis in certain respects. However, the appearance of fever and leukocytosis within such a short time after the onset, the relation of the pain to breathing and the delay in the development of the electrocardiographic signs indicate that the patient had pleurisy followed by pericarditis.

4 Mediastinal Lymphadenitis—Although postmortem examinations teach us that infections in the lymph nodes of the mediastinum are of common occurrence, little is known about the clinical picture they produce. In view of the frequency of mild pain in the neck in patients with cervical adenitis, it seems probable that obscure minor discomfort in the chest, developing in association with infections of the respiratory tract may result from swelling of the mediastinal lymph nodes. The following patient had discomfort which is believed to have been related to infection of these structures.

CASE 4—A white man aged 29 came for examination because of supposed heart disease. He complained of substernal pain which had first been noted seven months before, had disappeared after three weeks and had recently recurred. This pain was sharp and cutting in character and appeared especially when he was out in the cold air or when he exerted himself. He had also noted it on coughing. Several weeks previously he had had pain in the right axilla on deep inspiration as well as on coughing. Examination of the heart revealed no abnormalities. An electrocardiogram was negative except for a diphasic T wave in lead 4-F. A roentgenogram of the chest revealed typical lesions of tuberculosis, with cavitation at the right apex. There was also some increase in hilus markings.

It seems probable that in this case the substernal pain was related to infection in the mediastinal nodes (or mediastinal pleura) secondary to pulmonary tuberculosis. Similar discomfort may be observed in patients with nontuberculous infections of the respiratory tract. The following case is an example.

CASE 5—A white man aged 63 complained of "tightness and heaviness" in the upper substernal region. This was brought on by coughing and disappeared within a few minutes after coughing was stopped. He had had a chronic cough since he had pertussis at the age of 3 and he also suffered from recurrent sinusitis. The heart was negative to physical examination, but examination of the lungs revealed scattered squeaking rales and some moist rales at the bases. A roentgenogram of the chest displayed a decided increase in bronchial markings. An electrocardiogram was normal. Walking up four flights of stairs caused dyspnea but no pain.

Although this patient's pain was substernal, the only definite findings were those of bronchitis and bronchiectasis. Presumably, infection in the mediastinal lymph nodes had occurred and was responsible for the discomfort.

5 Penetrating Diseases of the Aorta—Any condition which causes rupture of the aortic walls leads to excruciating pain resembling that seen in certain cases of myocardial infarction. During the past several years numerous cases of dissecting aneurysm with pain of this type have been reported. More rarely such pain may be caused by rupture of the aorta due to necrosis of the medial coat, without the formation of a dissecting aneurysm. Although syphilitic aortitis, when not complicated by aneurysm, aortic insufficiency or narrowing of the orifices of the coronary arteries, is ordinarily a painless disease, saccular aneurysm may induce intense pain due either to pressure on sensitive structures or to erosion of the aortic wall by the syphilitic process. Porter⁵ has recently reported a number of cases of rupture of a syphilitic aneurysm into the pulmonary artery and has described the syndrome so produced. The following case, which represents an example of this syndrome, displayed certain features which were strongly suggestive of coronary artery disease.

CASE 6—A white man aged 69 complained of attacks of pain in the chest of one year's duration. The pain was sharp and knife-like and lasted only a few seconds. The pain was not related to exercise, emotion, eating or any precipitating factors which could be determined. Examination revealed hypertension, much cardiac enlargement, congestive failure, arteriosclerosis and striking elevation of the S-T segment, with absence of the R wave in lead 4. There was minimal fever but no leukocytosis, the sedimentation rate was normal. After a week's hospitalization the signs of congestive failure were diminished and the abnormalities in lead 4 were much less striking. Fluoroscopic examination at this time showed cardiac enlargement and pronounced dilatation of the aorta. Wassermann and Kahn tests were negative. He continued to have attacks of pain in the chest, left arm, upper abdomen and back. The pain was not related to exertion or other precipitating factors, and relief by glyceryl trinitrate was questionable. He had several attacks of severe intensity which lasted twelve or more hours and were thought by his physician to be due to coronary thrombosis. During one of these seizures he was admitted to the hospital in a state of circulatory collapse, the blood pressure being 105 systolic and 50 diastolic, as compared to 180 systolic and 140 diastolic on the previous hospital admission. On this second admission a basal systolic murmur, which had been faint when he was previously seen, was rather loud and was well heard in both the pulmonary and the aortic areas. The murmur was higher pitched than it had been previously. He died in collapse within a few minutes after this admission to the hospital and at autopsy was found to have syphilitic aortitis and an aortic aneurysm which had ruptured into the pulmonary artery. The heart was moderately enlarged but no myocardial scars were seen, there was no evidence of infarction and the coronary arteries revealed no narrowing and only minimal atheromatous changes.

In this case the changing character of the electrocardiogram and the presence of severe pain led to an erroneous diagnosis of coronary thrombosis. With proper interpretation of the history this mistake should have been avoided because of the fact that none of the numerous attacks of pain had been related to effort. Although no diastolic murmur was heard on the final admission, the patient was in collapse and even in this

⁵ Porter W. B. The Syndrome of Rupture of an Aortic Aneurysm into the Pulmonary Artery. *Am Heart J* 23: 468 (April) 1942.

state he had a high pulse pressure. This finding should perhaps have led to the suspicion that a communication existed between the aorta and the pulmonary artery.

The conditions which have been considered thus far have been of thoracic origin. Attention may now be focused on a group of abdominal disorders which may simulate coronary disease.

6 Duodenal Ulcer—Although in most cases peptic ulcer is associated with a characteristic train of symptoms, there are exceptional cases in which the pain may be felt in the chest and confused with that of angina pectoris. An instance follows.

CASE 7—A white man aged 63 complained of a heavy feeling and mild pain in the lower substernal region and in the precordium. This came on shortly after meals and was benefited by soda and by atropine. On several occasions this feeling of heaviness radiated to the left arm. Discomfort was never related to effort and always came on soon after eating. There was no story of relief by food. Physical examination was negative, as was the electrocardiogram. Examination with the roentgen ray revealed a normal heart but showed well defined pylorospasm and a filling defect in the duodenum which was interpreted as a healed duodenal ulcer. Atropine produced complete relief of symptoms when taken regularly in adequate doses.

The mechanism of pain in this case was apparently different from that in the usual ulcer case. Pylorospasm seemed to be the chief factor and, as occasionally happens, the pain produced by it was felt in the chest rather than in the abdomen. This led the patient, who was a physician, to suspect coronary disease. The tendency to emphasize the significance of location and radiation of chest pain rather than the importance of the circumstances under which it occurs is a common cause of errors in diagnosis.

7 Pylorospasm Secondary to Disease of the Gallbladder—Ordinarily, discomfort associated with cholelithiasis and chronic cholecystitis tends to be localized on the right side of the body. There are, however, exceptional instances in which these disorders may be associated with pain radiating to the left shoulder and arm. The following case is an example.

CASE 8—A white man aged 56 complained of "heart trouble." For several months he had had occasional attacks of mild pain in the left side of the chest under the clavicle with occasional radiation into the left side of the neck and down the left arm as far as the hand. The discomfort consisted of a feeling of tightness and fullness. It was not related to exertion, to breathing or to mental stress and was often completely relieved by belching.

Twenty years previously he had had an attack of severe cramplike epigastric pain which required morphine hypodermically for relief and was associated with nausea. Since then he had had a number of such attacks and in the intervals had noted considerable belching and vague abdominal distress.

Examination of the cardiovascular system was negative except for the blood pressure, which was 154 systolic and 91 diastolic. Slight tenderness was noted under the right costal margin and somewhat more tenderness in the midepigastrium just above the umbilicus.

The electrocardiograms showed no significant abnormality in either the precordial or the limb lead. Cholecystograms revealed a nonfunctioning gallbladder. Roentgen study of the gastrointestinal tract was negative except for well defined pylorospasm and aerophagia.

When the patient walked rapidly up three flights of stairs under observation there was no pain. However, distention of the stomach with air introduced through a duodenal tube caused the appearance of pain in the epigastrium, left side of the neck and left arm. The patient said that this pain was identical with that which caused him to come for examination.

The symptoms observed in this case are frequently observed in cases of pylorospasm, whether of functional origin, or accompanying organic disease such as peptic ulcer or cholelithiasis. Such symptoms frequently result in an erroneous diagnosis of angina pectoris. This error is unavoidable if too much stress is laid on the location, radiation and character of the pain rather than on the history of the behavior of the pain. The discomfort due to pylorospasm can often be reproduced by artificial distention of the stomach either with air or with water.

8 'Cascade Stomach'—In the course of a routine examination of the gastrointestinal tract, roentgenologists may observe that the barium first enters an upper pouch which is situated to the left and posteriorly and enters the main part of the stomach only after this upper pouch becomes filled. At this time the barium is seen to fall over from the upper pouch into the main part of the stomach, and the resemblance to a waterfall has led to the term "cascade stomach." The condition seems ordinarily to be accompanied by no symptoms or at most by minor digestive complaints. However, I have seen 3 cases in which cascade deformity of the stomach was associated with chest pain of a type which could readily be confused with the pain of coronary disease. The following case summary is illustrative.

CASE 9—A white man aged 37 complained of heart trouble. All his life he had had some skipping of the heart and recently he had become increasingly heart conscious having been made so by an attack of violent pain in the anterior lower left part of the chest. This pain came on when he was stooping over to tie his shoes, it lasted for about thirty seconds and was associated with such weakness that he fell to the ground and thought that death was imminent. The pain was described as being very severe and of cramping and tearing character. It did not radiate to the shoulder or arms. He led an active life and had never had pain in the chest on exertion. For several years he had had attacks of nausea and vomiting coming on almost daily about an hour after breakfast.

Examination of the cardiovascular system revealed no abnormality except a blood pressure of 150 systolic and 95 diastolic. There was slight tenderness in the epigastrium in a localized area. The electrocardiogram was normal in all respects. Fluoroscopic examination of the stomach was reported as follows: "As barium passed to the stomach it accumulated in the cardiac end which dilated into a large sac in the posterior position. It was not until this dilated sac became about half full that any barium passed over into the body of the stomach. At the junction of the body and the dilated cardia there was a definite constriction with a lumen of perhaps an inch in diameter. This constricted area was examined closely for visualization of an ulcer but none could be found. Except by overflow no barium passed into the body of the stomach in the erect position. When the patient was placed with his face down on the table all the barium was found to be in the body of the stomach and passed on into the duodenum in a normal fashion. The following day the fluoroscopic examination of the stomach was repeated, with the following results.

With the patient in the erect position the barium was swallowed, and at this time the stomach was normal in appearance and showed only the slightest tendency toward cascade. There was none of the spasm which, on the previous day, had elevated the body of the stomach and constricted it at the junction of the cardia and the body. The patient was completely relaxed at this examination and there was no nausea on filling or imminent vomiting as had been noted on the previous day after swallowing the barium.

The only explanation which could be found for the pain in this case was the abnormal degree of spasm between the cardia and the body of the stomach. Two other cases presenting a similar association of cascade

stomach and pain simulating coronary disease have been observed. Since, in all three instances, the pain responded satisfactorily to measures directed at the gastrointestinal rather than at the cardiovascular system, there would seem to be no doubt that cricoid deformity of the stomach, in certain cases leads to pain in the chest.

9 Diverticulum of the Stomach—I have seen only 1 case in which a diverticulum of the stomach caused chest pain. This was observed in consultation with Dr Wingate Johnson, to whom I am indebted for the following facts:

CASE 10—A man aged 54 complained of recurrent attacks of severe "grabbing" pain beneath the middle and lower sternum, radiating to the left arm and rarely to the right arm. The pain, which had been present intermittently for twelve years, did not usually appear during effort but frequently came when he was fatigued after effort, and especially shortly after eating. It was severe, frequently requiring morphine for relief, and appeared in spasms which lasted a few minutes and continued to occur at intervals of ten or more minutes for a period of several hours. Physical examination revealed no evidence of cardiovascular disease. There was pronounced malnutrition because the patient, having learned that eating induced his pain, had taken little food. An electrocardiogram revealed no significant change other than a tendency toward right axis deviation.

Walking up two flights of stairs caused weakness and fatigue but no pain and only slight panting. Fluoroscopic examination revealed a small, centrally placed heart with normal pulsations. A large diverticulum about 4 cm in diameter was found in the upper part of the stomach. This was subsequently removed at operation.

In this case the pain bore a close resemblance to that of angina pectoris in location, radiation and character. However, the conditions causing the pain were different, there being no relation to effort and a definite relation to meals. The symptoms resembled closely those of esophageal hiatus hernia, as recently described in detail by Jones.⁶

10 Dextrose Deficiency—In cases of diabetes and coronary arteriosclerosis the administration of insulin may precipitate attacks of angina pectoris. Sippe and Bostock⁷ have pointed out that spontaneous hypoglycemia may induce attacks in persons with coronary disease. However, it does not appear to be generally recognized that chest pain, not anginal in type and not associated with a grave prognosis, may also occur as the result of dextrose deficiency.⁸ An example follows:

CASE 11—A white man aged 49 complained of recurrent attacks of weakness associated with a "sinking feeling" and with precordial pain radiating to both shoulders. These seizures had never appeared shortly after meals, they usually occurred three to four hours after eating and on several occasions had awakened him in the middle of the night. The pain was rather mild but had led him to suspect that there was heart disease. This suspicion was confirmed in his own mind when a physician made an electrocardiogram and told him that it showed trouble with the circulation to the heart. There was one other important point in the story, which was the patient's

insistence that his "spells bore no relation to physical activity and that he was able to walk rapidly, even up hill or up stairs without dyspnea or discomfort."

Physical examination of the heart revealed no abnormality. Electrocardiograms were negative in the limb leads, but all the precordial leads displayed slurring of the QRS complex and inverted T waves. When questioned about any previous disease of the lungs or injury to the chest the patient at first gave a negative history but later remembered that several years before he had had an airplane accident and had fractured several ribs by striking the left side of his chest against the control stick. Investigation of the gastrointestinal tract with the roentgen ray yielded negative results. A dextrose tolerance test was done with the following findings: fasting blood sugar 83 mg per hundred cubic centimeters, thirty minutes after dextrose 160 mg, one hour 178 mg, three hours 69 mg and four hours 81 mg. The administration of 15 units of insulin produced a seizure of weakness and precordial discomfort. The patient stated that this induced attack was similar to the spontaneous seizures. When a low carbohydrate, high protein diet with intermediate feedings was prescribed the symptoms improved, recurring only when he violated his diet. One year later he was still almost completely relieved.

On superficial analysis the combination of precordial pain radiating to the shoulders, a "sinking feeling" and well defined abnormalities in the precordial leads of the electrocardiogram might seem to indicate definite coronary disease. However, more careful analysis led to the conclusion that the symptoms were related to a state of mild dextrose deficiency, while the alterations in the electrocardiograms could be ascribed to a healed contusion of the heart. Beck⁹ has described similar electrocardiographic changes occurring subsequent to nonpenetrating injury to the chest.

COMMENT

No attempt has been made to present a comprehensive discussion of the various conditions which may cause pain in the chest. My purpose has been rather to select a few conditions which seem to illustrate the importance of proper evaluation of the patient's story. Frequently, objective methods of examination are of the greatest value, occasionally, however, they may yield negative results and the physician may be tempted to make the assumption, often unjustified by subsequent events, that the patient's complaints are entirely of psychogenic origin. Furthermore, information that is obtained by objective methods may actually be misleading unless it is correlated with the history. (In case 11, for example the electrocardiogram when considered alone and without relation to the story of previous injury to the patient had led to an erroneous diagnosis.)

Another serious dilemma occasionally results from too great reliance on objective tests. This occurs when the patient has two different conditions simultaneously, both of them causing pain in the chest. Under such circumstances the objective methods of examination may reveal evidence of only one of them, and this may be the least important of the two. In the middle aged, obese man the coexistence of gallbladder disease and angina pectoris is rather frequently observed. Both of these conditions may cause chest pain. If, as is occasionally the case, the electrocardiogram happens to be within normal limits while the cholecystogram is abnormal, the physician may make the diagnosis of the

6 Jones C M. Hiatus Esophageal Hernia. *New England J Med* 225: 963 (Dec 18) 1941.

7 Sippe C and Bostock J. Hypoglycemia. Survey and Account of Twenty Five Cases. *M J Australia* 2: 302 (Sept 2) 1933.

8 The term dextrose deficiency rather than spontaneous hypoglycemia is used because patients differ considerably in the level of blood sugar at which symptoms develop and many patients suffering from symptoms of dextrose deprivation may have blood sugar levels only slightly below the normal range.

9 Beck C S. Contusions of the Heart. *J A M A* 101: 109 (Jan 12) 1935.

abdominal disorder and overlook entirely the existence of the coronary disease, which offers the greater threat to the patient's life.

In deciding whether a given pain represents angina pectoris the physician should not put too much emphasis on the location or radiation of the discomfort. In most of the cases which have been cited the pain corresponded in these respects to that of angina pectoris. The severity of the pain likewise is of relatively little value in diagnosis because the discomfort may be rather severe when its cause is inconsequential and may be mild in fatal cases of angina pectoris. Even the character of the pain is not a reliable guide. Several of the patients without angina described their pain as consisting of a feeling of heaviness, tightness or fullness.

The duration of the pain is of considerable importance in the exclusion of angina pectoris. A pain lasting only a few seconds or a pain lasting more than an hour is rarely due to uncomplicated angina pectoris although the pain of acute coronary thrombosis frequently lasts for many hours.

The most important feature of the history is the careful inquiry into the relation of the pain to the various body functions, and especially to muscular activity. If there is no relationship to exertion, it is highly improbable that the patient has angina pectoris, but even so the number of errors in diagnosis will be reduced if the physician will, when in doubt, note whether muscular exercise undertaken under observation induces the discomfort. Conceivably, exertion may be hazardous to a person with angina pectoris. However, if the history has been carefully taken and the exercise is adjusted so as to be minimal for this particular patient and is stopped the moment the discomfort appears, the risk is probably very small and, in any event, it is less than the risk involved to the patient in not having a correct diagnosis made.

It may be stated as a general rule that any pain in the upper abdomen, chest, neck, shoulders or arms which has a definite relationship to physical exertion should be considered as angina pectoris until proved otherwise. This rule is subject to certain rare exceptions, but these are not likely to lead to confusion. The pain of pleurisy and the pain associated with inflammation of the mediastinal lymph nodes may be exaggerated by exertion (case 4). In such instances the pain is usually sharp and has a definite relation to respiration. Such a relationship rarely, if ever, exists in the pain of coronary disease. Occasionally the pain of esophageal hiatus hernia may be worse on effort, as has been recently emphasized by Jones.⁶ However, the relationship to effort is not as striking and the discomfort cannot be regularly reproduced by walking, while the story of relation to position and to eating will usually provide the proper clue.

The causes of pain in the chest are many, and the procedures which may be carried out in order to ascertain the exact cause are very numerous. Unless one is willing to subject every patient with a complaint of chest pain to a barrage of roentgenograms, chemical studies and other expensive procedures, one can avoid pitfalls only by a painstaking and elaborate history with especial emphasis on the relationship of the pain to various functions of the body. From such an analysis of the patient's story the correct clue can usually be obtained, and as a rule one or two additional studies will bring confirmation.

ABSTRACT OF DISCUSSION

DR FERDINAND F. SCHWARTZ, Painesville, Ohio. In my experience, chest pains are often due to allergy, especially allergy to nicotine. Today when females smoke as do males, doctors should keep in mind the possibility of an allergic reaction especially to nicotine in tracing down chest pains.

DR HENRY M. THOMAS JR., Fort George G. Meade, Maryland. Dr. Harrison has touched on only a few of the conditions other than coronary occlusion which produce pain in the chest. I have been impressed with the frequency of pain below the breast in women when there was no apparent reason for it, and I wonder whether Dr. Harrison has an adequate explanation. Many women complain of such pain, and on examination there is tenderness in the breast tissue. Two conditions have been seen at Fort Meade in young soldiers which are worthy of mention. One of them was an attack of interstitial mediastinal emphysema. This young soldier was engaged in a double time drill when he felt pain in his left chest which radiated to the shoulder and down the arm. He was studied for several days and no signs developed. He said "I can hear a sound in my chest." The ward surgeon listened and there was no sound. The man said "There is no sound when I sit up or stand up, but only when I lie down." The surgeon had the patient lie down and there was a loud crunching noise which occurred with each beat of the heart. Later he developed a little free air in the pleural cavity also. It all cleared up, and the symptoms disappeared. The other condition was an attack of agonizing pain that a young man had after sitting for some time in a bent over position. When he started to sit up, this pain struck him in front of the heart. He slumped down and in a minute tried again with the same result. Finally he straightened up, something snapped, and the pain disappeared. I believe that he had crossed two costal cartilages, which pinched and that as he stood up they became free and the pain disappeared.

DR WINGATE M. JOHNSON, Winston-Salem, N. C. A patient whom Dr. Harrison saw and whom I treated for some time, for eleven years had drawn total and permanent disability insurance for attacks of pain in his chest. But it was noticed that the attacks came on right after meals. X-ray examination showed a diverticulum at the cardiac end of the stomach, which pointed upward so that when he swallowed, food would be caught in it. He was operated on, the diverticulum was removed, and he is better but still has the habit of spasm and also the total and permanent disability.

DR CHAS. W. DAY, Indianapolis. I want to call attention to a condition that I find quite often. Intercostal neuralgia will cause much pain. X-ray examination will often reveal a metastasis of some kind into the spine. Dr. Johnson spoke about a diverticulum. About ten years ago I saw a man who would eat a meal and then would have a severe pain in his chest. We took a picture and found that a diverticulum had started just at the upper end of the esophagus and had run down to the arch of the aorta. It was impossible to operate. The patient was 63 years old. He died from starvation, because the diverticulum increased in size until he couldn't keep any thing in his stomach. So called intercostal neuralgia often is in fact a mediastinal reflex from some other condition.

DR EMILIO LEOPOLD HERBERT, Brooklyn. I was invited seven years ago to a party at which everybody drank beer. I did not care for beer, so I asked the lady if she had any wine. I was the only one who drank any of that homemade wine. I was a school medical instructor in Brooklyn. The next morning I was taken with an attack of pain in the heart. I came home and sent for a doctor, who made a diagnosis of coronary thrombosis. He gave me a hypodermic of a half gram of morphine, which relieved the pain. I was told to stay in bed for twelve weeks. I felt perfectly well after that. I rose out of bed on the third day and returned to work. A week later I had an electrocardiogram taken, and the doctor made a diagnosis of coronary occlusion. That was over six years ago. I had no more pain. I did not stay in bed three months and I am still very much alive.

DR F M POTTENGER, Monrovia, Calif. There is one kind of pain not mentioned by the speaker which I would like to discuss the recurrent pain over the lower portion of the chest of patients who previously have had pleurisy. Chronic inflammation of the pleura, as well as of other viscera, produces degenerative changes in the muscles, skin and subcutaneous tissue which are reflexly connected with the inflamed area. This type of pain varies. Sometimes it is severe, at other times it is only an ache. It is particularly necessary to recognize it when it involves the lower portion of the chest, because it often extends down over the abdomen, and the pain is sometimes mistaken for evidence of acute disease of the abdominal viscera. I have seen gastric ulcer, gallbladder disease and appendicitis not only suspected but operations performed to remedy these supposed conditions when no active disease was present the cause being the permanent injury to the nerves caused by the previous pleurisy. The degeneration which follows a chronic pleurisy is often seen as a distinct furrow following the nerve or nerves involved. The subcutaneous tissue not only loses its tone but actually atrophies and lessens. These same nerves that are involved in the degeneration often show pain. This pain is recurrent, the same as recurrent pain in rheumatism. It comes with changes in weather with menstruation, and when the patient is subjected to emotional and nervous stress. This should always be kept in mind when attempting to determine the origin of recurrent pain over the lower chest and upper abdominal areas. If degeneration with lessening of the thickness of the subcutaneous fat is found, one should suspect previous pleurisy even if no signs are found on auscultation. Sometimes lagging of the side weakness of the auscultatory note and stretching sounds or fine rales will be detected on deep breathing to help in the diagnosis. I have seen this years after the acute attack of pleurisy subsided.

DR MEYER GOLOB, New York. There is an explanation why in the presence of a lesion in the right upper abdominal quadrant pain may be referred to the precordium. The late Dr David Riesman of Philadelphia said that if a patient complains of pain below the left diaphragm, think of the heart; if he complains of the heart think of the stomach; if he complains of both think of the thyroid. I want to make particular mention of right upper abdominal disease with referred symptoms elsewhere. There are many such cases. I have under my care patients with definite cholecystopathy, with symptoms distant to the site of the lesion. One case of calculous cholecystitis had a classic clinical picture of precordial pain suggestive of a lesion above the left diaphragm. There was, however, a normal electrocardiograph. There are cases, of course, in which concomitance must be thought of. One may have a gastropathy or a cholecystopathy, with or without stones, and have in addition vascular disturbance coronary artery disease, for instance. From the standpoint of age incidence both gallbladder disease and cardiovascular disease are more common in the aged. The emphasis is on the referred pain. If the patient has pain in the precordium, with a silent right upper abdominal quadrant, one must think of eliminating a right upper abdominal lesion with referred pain to the precordium.

DR TINSLEY R HARRISON, Winston-Salem, N C. Certainly chronic pleurisy may cause pain in the precordium which may be confusing, because there are often no physical signs of the pleurisy, and the x-ray evidence may be dubious. Gallbladder disease likewise may cause pain that is felt only in the substernal region rather than in the classic area. It is important to emphasize the frequency of intercostal neuralgia as a cause of pain. In my experience, tobacco has been an uncommon rather than a common cause of pain in the chest. The point raised by Dr Thomas about the frequency of this apical pain in women is an important one, and I don't think any one can answer his question as to what causes it. Occasionally this pain seems to arise in the breast tissue itself. There are a certain number of these women who have precordial hyperesthesia and who have also a "tight feeling" in that region, in whom one can reproduce the pain by distending the colon or the stomach with air. Even so we are still left with a large number of these people in whom we can't account for the pain and in whom we are all

guilty in origin when it would be wiser to say "pain, cause unknown." The situation as regards coronary thrombosis and angina pectoris has changed completely in the last generation. Twenty years ago these conditions were overlooked with great regularity. Now they are all too frequently diagnosed when they do not exist. This error will probably continue to be made until more cases are studied carefully in people who do not have angina pectoris or coronary thrombosis but who have pain simulating them and until we are able to correlate the clinical picture of such patients with autopsy findings. It is perhaps worth while to reemphasize that, although these various conditions which have been mentioned are conditions which cause confusion with angina pectoris and coronary thrombosis, if one relies on the location and radiation of pain, such confusion can usually be avoided if one centers one's attention on the conditions which produce the pain. I know of no other conditions in which the pain is likely to have the same relation to effort as is true in the case of angina pectoris. A careful history is still and probably always will be the most important method of diagnosis in patients with pain in the chest.

THE EFFECT OF MORPHINE AND PROSTIGMINE METHYLSULFATE

ON MEASUREMENTS OF PAIN THRESHOLD

HOWARD L ANDREWS, PH D

Biophysicist United States Public Health Service

LEXINGTON, KY

Clinical reports have been presented which suggested that the combination of morphine and prostigmine methylsulfate has definite therapeutic advantages over morphine alone.¹ The investigations reported in the present paper were undertaken in the hope of obtaining more objective evidence regarding this reported potentiation.

METHODS

The Hardy-Wolff method of measuring pain thresholds was used throughout the study. The stimulus intensity at the threshold was measured either with a radiometer or with a wattmeter connected in the lamp circuit, it having been previously shown that there is a linear relationship between these variables over a wide range of intensities.² At each test several determinations were made until a satisfactory threshold was established. The desired dose was then administered subcutaneously and the pain threshold redetermined at intervals of fifteen minutes until it returned to its original value, or until it was evident that the drug given had not produced an effect. Addicts receiving repeated doses were given the drugs at 6 a m, 11 a m, 5 p m and 10 p m. On test days the 6 a m dose was postponed until a threshold was established at about 8 a m, so that these men were about ten hours abstinent at the start of the test. Except for the patient who received repeated doses, no subject knew what drug he received and in fact did not know that prostigmine methylsulfate was being studied.

RESULTS

It was first established that prostigmine methylsulfate alone has no threshold raising effect in doses up to 1 mg. These doses were studied for two hours after admini-

istration and in no case was there any significant change in the pain threshold

Two normal persons with no history of morphine addiction were then each given 8 mg of morphine and 0.5 mg of prostigmine methylsulfate. A third normal person received 0.5 mg prostigmine methylsulfate ninety minutes after 8 mg of morphine had been given,

Chart 1—The percentage of rise in pain threshold over the preinjection value is plotted against the time after administration. The slightly increased effect with the combined medication is of no practical significance.

at a time when the threshold raising effect of the morphine was nearly maximal. The results of these tests are shown in chart 1 and are compared with the curve obtained previously on normal persons with 8 mg of morphine.

It is evident that when 0.5 mg of prostigmine methylsulfate is administered with morphine there is only a slight change in the pain threshold curve. When the prostigmine methylsulfate is given ninety minutes after the morphine there appears to be a rapid decrease in the threshold.

Fifteen patients who had been addicted to but had received no regular doses of narcotics for at least six months were tested with 20 mg of morphine plus 1 mg of prostigmine methylsulfate and 20 mg of morphine for comparison. At least two weeks elapsed between successive doses. In about half of this series the morphine was given first and in the rest the combination was first tested. In many instances the entire test was repeated, always with intervals of two weeks between doses.

Chart 2 shows the comparative mean threshold raising effects of the two drugs. It has been shown³ that in general a person who has previously been addicted

Chart 2—Pain threshold raising effect in former addicts. There is a definite potentiating action but the effect is still abnormally low.

shows a greatly reduced response to the pain threshold raising effect of a dose of morphine. It is evident that there is an enhanced effect when prostigmine methylsulfate is added to the morphine, but the mean curve is still abnormally low.

Two prisoner patients, who volunteered for the study, were used to test the development of tolerance to repeated doses. Each received four doses of morphine daily and, within limits, was allowed to increase his dose as tolerance developed. One received only morphine while the other received either 0.25 or 0.5 mg of prostigmine methylsulfate with each injection. The 2 men increased their doses at about the same rate, 1 reaching a daily dose of 220 mg on the fifty-sixth day and the other 200 mg on the fifty-eighth day. Measurements of the pain threshold raising effect were made at intervals the amount currently chosen by the patient being used as the test dose.

It is interesting that both men so increased their doses that the magnitude of the pain threshold raising effect remained approximately constant. The area under each of the percentage rise-time curves was measured with a planimeter to obtain the total effect of the dose in percent hours. To eliminate the factor of variable dosage each area thus obtained was divided by the dose used to obtain the effectiveness of that particular dose. This will then be expressed in percent hours per milligram.

When the logarithm of these figures is plotted against the time of administration a nearly linear relationship is obtained (chart 3). The slope of these lines is a measure of the rate of developing tolerance. It can be seen that there is a slight difference in favor of the combined medication, but in view of the fact that only 1 sub-

Chart 3—The development of tolerance with repeated doses. The natural logarithm of the effectiveness of each dose tested is plotted against the corresponding number of days the drugs had been administered.

ject was used it seems probable that there is no significant difference in the rates at which tolerance developed.

COMMENT

Most of the results reported here are on small groups, but in view of the possible dangers attending administration of morphine it seemed undesirable to make these groups larger. It appears from the results that there may be a slight increase in the effectiveness of morphine when prostigmine methylsulfate is added, but in every test this effect was small and of no practical importance. If prostigmine methylsulfate had a strong potentiating action, such for example as doubling the morphine effect, it would seem that this would have been observed even with the present small groups. The greatest potentiation was observed in the former addicts, but this group has been shown to react abnormally to morphine, and even here the effect is not great enough to be of practical importance.

It must be remembered that the clinical relief of pain by morphine is probably the resultant of several effects, the pain threshold raising action being only one of the components.⁴ The reaction to pain, presumably reduced by opiates, is difficult to quantify and has not been considered in the present study.

⁴ Wolff H G, Hardy J D and Goodell H. Studies on Pain Measurement of the Effect of Morphine, Codeine and Other Opiates on the Pain Threshold and an Analysis of Their Relation to the Pain Experience. *J Clin Investigation* 19: 659 (July) 1940.

CONCLUSION

It appears that the combination morphine-prostigmine methylsulfate is not significantly more effective in raising the pain threshold than morphine alone and that the addition of prostigmine methylsulfate does not appreciably change the rate at which tolerance is developed.

Clinical Notes, Suggestions and New Instruments

TORULA HISTOLYTICA MENINGOENCEPHALITIS

RECOVERY FOLLOWING BILATFAL MASTOIDECTOMY AND
SULFONAMIDE THERAPY. PRELIMINARY REPORTMARK MARSHALL M.D., AND R. WALLACE TEED M.D.
ANN ARBOR, MICH.

Human infection with the various pathogenic yeasts is not of frequent occurrence. This is particularly true of torulosis, which must be classed as an extremely rare disease. When it is considered that the torulae are found on normal skin, in the human throat and gastrointestinal tract, in milk, on various plants and in the bodies of many insects, as pointed out by Wade and Stevenson,¹ it is surprising that infection does not occur more often. When it has occurred, however, it has usually been fatal.

While in most of the cases reported there was involvement of the central nervous system, a few presented localized involvement in other parts of the body. In these cases the mortality has not been so great. Brewer and Wood,² for example, reported healing of a localized abscess over the dorsolumbar spine following incision and drainage. A patient with a torular pelvic abscess observed by McGehee and Michelson³ recovered following drainage and iodide therapy. Jones's⁴ case presented involvement of the palate and nasopharynx and was considered arrested following curettage, administration of iodides and roentgen therapy. Gill⁵ further discussed cases presenting involvement of the upper respiratory tract.

Reeves, Butt and Hammock⁶ reviewed the literature on torulosis of the central nervous system up to 1941, collecting 73 cases and adding 6 of their own. Neither they nor Wade and Stevenson¹ were able to discover any in which recovery had occurred. During 1941, however, 3 instances of recovery, or at least of remission, of the disease were reported. Binford⁷ reported the first of these. A man aged 41 was seen April 5, 1939, because of severe headache. After many examinations of the spinal fluid torulae were found, and treatment was limited to repeated lumbar punctures. On March 1, 1940 he was still having occasional headaches with stiff neck and 250 cells per cubic millimeter in the cerebrospinal fluid. At this time, torulae were not observed on direct examination, but a guinea pig died of torulosis following inoculation of the fluid.

The second case was reported by Toone.⁸ A Negress aged 18 was given potassium iodide on her first admission and was discharged improved two months later. After an interval of

eighteen months she was readmitted because of headache. The cerebrospinal fluid was under a pressure of 330 mm and contained torulae on direct examination.

The third patient, treated by Reeves, Butt and Hammock⁶ was a girl aged 15. In addition to evidence of disease of the central nervous system she also had empyema thoracis, for which an operation had been done, and a draining sinus persisted in the chest. She was admitted to the hospital on four occasions, on one of which exploration for brain abscess was carried out but none was found. She was given torula antigen and sulfapyridine. She was definitely improved following her last hospital stay and was able to get about, although small numbers of torulae could still be found.

In a case reported by Stiles and Curtiss⁹ sulfanilamide was given as a last resort but the patient died the following day.

Since none of the cases mentioned can be considered as having been cured and since our experience with the sulfonamides was so dramatic, we believe that our case offers sufficient interest to warrant a report, which is considered preliminary.

REPORT OF CASE

D. C., a white girl aged 9 years, was admitted to St. Joseph Mercy Hospital Jan. 13, 1942 because of headache, fever, nausea and vomiting.

The parents had noted during the past five years that the child was deaf, and her teacher had placed her in the front row in the schoolroom. Otorrhea had never been present, and a cause for the hypacusis could not be assigned. She had pertussis at 6 years followed by asthma, which disappeared after the next frost. At 7 the tonsils and adenoids were removed, and following this procedure the deafness was even more noticeable. A few months after the operation she had mumps.

No further trouble developed until about Dec. 1, 1941, when she caught cold and complained of earache several times. The family physician examined the ears but found no abnormality and prescribed ear drops. She was kept in bed and was gradually improving when about December 20 her condition became worse, with high fever, cough, nasal discharge and occasional attacks of pain in the ears. A diagnosis was made of influenzal pneumonia. For a week she remained quite ill and then began to improve.

On the night of Jan. 1, 1942 she had a disturbing "nightmare," which was followed by severe frontal headache. The mother noted the following morning what she thought were a few drops of pus on the child's pillow, which she assumed came from the left ear. At no time, however, was pus visible in either canal. The headaches became worse daily, and sedatives were required constantly. Frequently the child would cry out loudly with the pain, holding her head in her hands. Three days prior to admission she began to be nauseated and vomited frequently. During the twenty-four hours previous to admission she was unable to hold anything on her stomach, vomiting, in fact, when the stomach was entirely empty. She had become extremely irritable in the ten days prior to admission, and the mother had noted a decided change in her personality and mental acumen. No complaint relative to the ears had been made during this time, and there was no swelling or tenderness behind the ears.

On examination January 13 the patient appeared to be exceedingly ill. The skin was dry and hot and the lips were covered with sordes. The cheeks were flushed and the eyes had an anxious expression. The child was apathetic most of the time but on any attempt at examination would cry out loudly and insisted on having her mother with her constantly. On being questioned about the pain she passed her hand over her forehead but denied that there was any pain either in or behind the eyes.

The nares were clean. The septum was straight. The turbinates were slightly congested but no obstruction of the nasal fossae existed. A small amount of mucopurulent secretion was present in the posterior ethmoid region on both sides. The tongue was dry and heavily coated. The teeth were

normal. The pillars were scarred and the tonsils surgically absent. A few small glands were present in the neck but none were tender. The right external auditory canal was clean, but the drum membrane had a peculiar appearance. It was thin, transparent and gray but had no luster or cone of light. The short process was visible, but posterior to this the membrane seemed to fade into the posterior-superior canal wall which appeared to be definitely sagged. No perforation or discharge was noted. The left external canal was red, and a small amount of caseous material was noted in the fundus of the canal. Definite sagging was noted and no landmarks could be made out. The drum membrane was red but no perforation could be seen. No tenderness or swelling was present over either mastoid. Hearing tests were difficult because of the lack of cooperation, but it was apparent that the child could hear a whisper at about 3 feet in both ears. Nuchal rigidity was not present, but the Kernig sign was slightly positive. The eyegrounds revealed papilledema, with scattered retinal hemorrhages.

Roentgen examination revealed normal paranasal sinuses. Both mastoids revealed clouding of all cells, with indistinctness and central softening.

A diagnosis of coalescent mastoiditis, mixed and bilateral, with probable localized meningitis and extreme dehydration was made.

The patient was admitted to the hospital at once and placed on a regimen of hydration for thirty-six hours. On January 15 the left mastoid was opened. All of the cells were dissected and filled with a thick, stringy mucopus, which was later reported to be sterile on culture. The tegmen antri was partially destroyed, and through the perforation a dural granuloma about 5 mm in diameter extended into the antrum. A small amount of pus was present in the granuloma. The dural plate was removed widely in all directions around the perforation until normal dura was seen. On palpation, the dura was as tense as a tennis ball, giving evidence of a very high intracranial pressure. The sigmoid sinus plate was apparently normal, and the sinus was not exposed. After all cells were cleaned out and the tip was amputated the wound was filled with 4 Gm of sulfanilamide powder and closed in layers. A small Penrose drain was led out at the tip. After a dressing was applied lumbar puncture was done. The fluid came out in a stream under great pressure, which was impossible to measure, since it ran out the top of the manometer (540 mm). About 30 cc of clear fluid was removed, after which the pressure was normal.

As soon as the child had reacted she was placed on sulfadiazine therapy under the impression that the findings in the mastoid explained the symptoms and that sulfonamide therapy would prevent the localized meningitis from becoming general. The following day the temperature rose to 101 F rectally and the child was drowsy. There was definite nuchal rigidity and the Kernig sign was positive. On January 17 Dr S C Howard, director of the laboratory, reported that the cerebrospinal fluid showed large numbers of yeast cells on direct smear of the centrifuged sediment. These were doubly refractive budding forms which he identified as *Torula histolytica*. A spinal tap on the same day revealed clear fluid, again under great pressure and containing large numbers of *torulae*, which were later grown on culture.

January 20 the child seemed much improved. She had no headache, stiff neck or positive Kernig sign. The mastoid wound was healing, with all drainage and sutures out. The canal was dry. The question now arose as to the disposition of the right mastoid, since, according to the literature, the prognosis was hopeless. It was decided, however, that everything that was possible should be done for the child, in spite of the dark outlook. In addition, there was the remote possibility that the mastoids might have been the focal origin of the disease.

Consequently, on January 21 the right mastoid was operated on and found to be diseased, as was the left, with the exception that no dural granuloma had formed. Tissue was removed from the mastoid and later reported as chronic granulation by Dr Howard. No *torulae* were seen. A spinal puncture was

done at the conclusion of the operation and the pressure was found to be normal. Cultures of the spinal fluid taken at this time and planted on special mediums failed to show any growth at the end of three weeks.

Following the operation the patient's condition was downhill for three days, and the parents were advised of the prognosis. January 25, however, she lost her drowsiness and began to improve. The ears healed and the general condition appeared satisfactory. Sulfadiazine was continued after the second operation but was stopped on February 2 when she was discharged from the hospital. At this time she was afebrile, the ears were dry and the mastoid wounds healed. She had no headache, stiff neck or positive Kernig sign and her excessive irritability had disappeared. Her mother believed that her mental reactions were quite normal. The hearing was essentially normal in both ears.

On February 5, however, the child was returned to the hospital with the same symptoms for which she had originally been admitted—headache, nausea, vomiting and a regressive personality change. She was uncooperative and resisted all attempts at examination. The temperature was 100.4 F. She complained of diplopia whenever she looked at an object more than 3½ feet away. Nystagmus could not be made out. The neck was not stiff, but the Kernig sign was slightly positive. Both auditory canals were clean and the mastoid wounds were healed. Spinal puncture released fluid (clear) under a tension of more than 600 mm. Fifteen cells per cubic millimeter were present, mostly lymphocytes. *Torulae* could not be identified either on direct examination, culture or animal inoculation.

It was obvious that our optimism in discontinuing medication and discharging the patient three days previously had been excessive. Therefore she was put back on sulfadiazine therapy and by February 7 the headache, fever, nausea and vomiting had disappeared. The mental condition was slowly returning to normal. There were still evidences of choked disk and retinal hemorrhages in both eyes but it was not felt that these were any worse. On February 12 another lumbar tap was done and clear fluid under more than 600 mm of pressure was obtained. After 20 cc was removed the pressure dropped to 170 mm. Only 8 cells per cubic millimeter were present, but no *torulae* were seen either on smear or on culture.

With no guidance from the literature in regard to further therapy, several authorities on the sulfonamides, including Dr Perrin Long of Baltimore were consulted. It was decided to keep the child on sulfadiazine for a total of six to eight weeks, if possible. A dose of 0.5 Gm every four hours had been found sufficient to keep the blood level at about 6 per cent and the spinal fluid level at 4.75 to 5 per cent.

On February 16 the girl was discharged from the hospital although the same dosage of sulfonamide was continued at home. She returned to the clinic twice a week for blood examinations and general observation. Spinal taps were done on February 19 and 27 and on March 9, and at each instance a pressure of more than 600 mm was found, although less was needed to reduce the pressure to normal at each succeeding tap. After this, with improving vision and clearing of the retinal hemorrhages, it was considered unnecessary to continue the punctures further.

On March 21, she began to show a drop in the total number of white cells and in the percentage of granulocytes, and the sulfadiazine was discontinued after forty-four days of continuous administration. In the belief that it might be advisable to continue some form of medication, potassium iodide was prescribed, which she is still taking and probably will continue to take for another two months on a purely empirical basis.

The child remained symptom free until April 26, when an acute infection of the upper respiratory tract developed. She was kept in bed at home but on April 30 began to complain of pain in the right ear and mastoid region. There were redness and swelling in the mastoid wound, but since there was no evidence of abscess formation she was placed on sulfadiazine therapy. In three days, the pain, swelling and fever subsided and surgery was not necessary. No headache or stiff neck was present at any time, and it was not felt that the symptoms were due to an exacerbation of infection in the brain and meninges. The child was discharged from the hospital on

May 2 and has been well ever since. At the present time (June 5) she is up and about as usual, with no evidence of disease.

COMMENT

At the first examination it was felt that this was a relatively simple case of masked, bilateral mastoiditis with localized meningitis. The finding of torula came as a distinct surprise and called for a complete reevaluation of the case. It was thought that the torula might have reached the meninges via the mastoids, but this opinion had to be abandoned in view of the complete absence of the yeast in either culture or histologic study of tissue from the mastoid. Consequently it came to be believed that the mastoid infection was a purely coincidental affair, possibly antecedent but having little or no influence on the meningoencephalitis. The history of deafness was interesting but after healing of the mastoid wounds tests showed practically normal hearing. No attempt is made to evaluate this portion of the history. The decided changes in the child's mental reaction following sulfadiazine therapy were most interesting as was the regressive change following the discontinuance of the drug after the first admission. The absence of torula in the spinal fluid since about February 1, along with clinical recovery, lends us to the hope that the child may be completely cured. This is further borne out by the fact that she recently passed through an acute infection of the upper respiratory tract with no signs of an exacerbation of the encephalitis.

Evidence that mycotic infections as a class may be treated successfully by the sulfonamides is offered by Poulton,¹⁰ Walker,¹¹ Bailey,¹² Miller and Fell,¹³ Dorling and Eckhoff,¹⁴ Ogilvie¹⁵ and Dobson, Holman and Cutting,¹⁶ in whose cases complete recovery from abdominal actinomycosis followed sulfonamide therapy. Several of the patients had been treated by the usual methods, such as surgery, iodides and roentgen rays, and were losing ground. Healing promptly followed the institution of sulfonamide therapy. Recovery from actinomycosis involving the cervicofacial region and thorax has been reported by Dobson, Holman and Cutting,¹⁶ Morton,¹⁷ Sudler and Johnson¹⁸ and Jorge, Browne and Mealla.¹⁹

In addition, Hemmens and Dack²⁰ reported cure in rabbits of otherwise fatal experimental infections with *Bacterium necrophorum*, a close relative of the Actinomycetes, following sulfonamide therapy. Van Bree²¹ reported recovery in a case of moniliasis Schroeder²²—in one of malignant blastomycosis and Dixon²³ in one of Madura foot (*Actinomyces madurae*) as a result of the same treatment.

It is therefore evident that another large and serious group of diseases the mycoses, may be amenable to sulfonamide therapy. One has a distinct feeling that the high mortality of the past will give way to a much better experience in the near future.

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition—Ed.

The successful prosecution of this war, as stressed by Herbert Hoover¹ during World War I, imposes a responsibility on the food exporting countries of the world, namely, that of providing adequate supplies of food for themselves and for their allies. There is no practical way to get food to any part of western Europe now except Great Britain without postponing the winning of the war, but when the war is won the additional gigantic problem will arise of finding food for much of Europe and for Asia. It is probable that many hundred million people will be starving then. It is presumed that half the populations of the occupied countries and Spain are starving now.

Vice President Henry Wallace^{1a} has estimated that the wheat in storage in Canada, the United States, Australia and Argentina would cover the import requirements of Europe for nearly three years. The amount of corn on hand is presumably as great. However, wheat and corn alone will not suffice. Excellent as they may be as foods, the newer knowledge of nutrition teaches that several vitamins and some protein fractions which wheat and corn alone cannot supply are needed to provide for adequate nutrition. It teaches, indeed, that providing ample calories in a diet which is limited in certain nutrients intensifies the need for missing nutrients.

A cursory survey of any bibliography on foods reveals that almost every living thing has graced man's bill of fare at one time or another. It also is apparent that primitive peoples, as a rule, have been fortunate in their food selections. The diets of those nations of the world which are most advanced in technological achievement suffer by comparison. Technology directed at the food supply has not been wisely guided, and the result is not a happy one. The dramatic improvement in the death rate throughout the so-called civilized part of the world can only partly be explained by improved nutrition in some sections of these populations. It is mainly due to the application of medical science, especially the application of public health and hygiene. The increasing incidence of degenerative diseases and high incidence of decay of teeth suggest that average vigor in the more civilized races has declined.

The several hundred delegates who attended the Washington Nutrition Conference in May 1941 approved recommendations relating to requirements

for good nutrition submitted by the Food and Nutrition Board of the National Research Council. These recommendations were reached after a careful review of all the evidence available. Submitted as a table of recommended daily allowances for specific nutrients (table 1), they call for protein of a type found best in dairy products and in meat or fish, for calcium, for iron and for several vitamins at specific levels for varying age and activity. While cereals occupy an important place in food economy, to meet these higher standards of nutritional economy more liberal allowances of dairy products, meat, fish, fruits and green or yellow vegetables than formerly were considered necessary will be demanded.

Sir John Orr, scientific adviser on nutrition to the war cabinet in Britain, expressed the opinion that the "Washington nutrition yardstick," as he termed the

market for dried skim milk is growing among commercial manufacturers of bread and several other processed foods, but a public demand for such a product has not existed. In the United States alone some fifty billion pounds of skim milk is largely wasted every year. How much of this is simply thrown away is not known. Much is fed to animals, but this is waste because the nutrients in skim milk, pound for pound, equal those of muscle meat, and it appears that 10 pounds (4.5 Kg.) of the nutrients of skim milk is required to produce 1 pound (0.5 Kg.) of food nutrients in the form of pork.² Other less costly feed would do as well for hogs.

The quart of liquid milk a day for children and the pint for adults, as recommended in much nutrition teaching, is more than many family budgets will allow, but why insist on liquid milk? Milk can be distributed

TABLE 1—Recommended Daily Allowances for Specific Nutrients
Committee on Foods and Nutrition National Research Council

	Calories	Protein Gm.	Calcium Gm.	Iron Mg.	Vitamin A International Units	Thiamine (B ₁) Mg.	Riboflavin Mg.	Nicotinic Acid Mg.	Ascorbic Acid [†] Mg.	Vitamin D International Units
Man (70 Kg.)										
Moderately active	3,000	70	0.8	12	5,000	1.5	2.7	18	70	†
Very active	4,000					2				
Sedentary	2,000					1.5	2.2	15		
Woman (60 Kg.)										
Moderately active	2,500	60	0.8	12	5,000	1.5	2.2	15	70	†
Very active	3,000					1.8	2.7	18		
Sedentary	2,100					1	1.5	11		
Pregnancy (latter half)	2,000	80	1.5	15	6,000	1.8	2.2	15	100	400-500
Lactation	3,000	100	2.0	15	8,000	2.0	3.0	20	150	400-500
Children up to 12 years										
Under 1 year §	100/Kg.	3.4/Kg.	1.0	6	1,500	0.4	0.6	4	20	400-500
1-3 years	1,000	40	1.0	7	2,000	0.6	0.9	6	35	
4-6 years	1,600	60	1.0	8	3,000	0.8	1.2	8	50	
7-9 years	2,000	60	1.0	10	4,000	1.0	1.5	10	60	
10-12 years	2,500	70	1.0	12	4,000	1.2	1.8	12	70	
Children over 12 years										
Girls 13-15 years	2,800	80	1.3	15	5,000	1.4	2.0	14	80	†
16-20 years	2,400	70	1.0	15	5,000	1.2	1.8	12	80	
Boys 13-15 years	3,200	80	1.4	15	6,000	1.6	2.4	16	90	†
16-20 years	3,800	100	1.4	15	6,000	2.0	3.0	20	100	

Tentative goal toward which to aim in planning practical diets can be met by a good diet of natural foods. Such a diet will also provide other minerals and vitamins the requirements for which are less well known. Reprinted from *THE JOURNAL*, June 7, 1941, page 920.

* Requirements may be less if provided as vitamin A, greater if provided chiefly as the provitamin carotene.

† One mg. of thiamine equals 333 international units; 1 mg. of ascorbic acid equals 10 international units.

‡ Vitamin D is undoubtedly necessary for older children and adults. When not available from sunshine it should be provided probably up to the minimum amounts recommended for infants.

§ Needs of infants increase from month to month. The amounts given are for approximately 6 to 8 months. The amounts of protein and calcium needed are less if derived from breast milk.

¶ Allowances are based on needs for the middle year in each group (as 2, 5, 8 and so on) and for moderate activity.
